(54) Title: A SECURE PAY-AS-YOU-USE SYSTEM FOR COMPUTER SOFTWARE

(57) Abstract

A method of renting software that relies on the reversal of encryption processes by the integration of secure processing into the system microprocessor of a user controlled data processing system. It consists of protected software objects, that in addition to being functionally limited to requires reversal of said limitation within the system microprocessor, they also have closely integrated information about conditions of use. This is used to distribute computer software on a large scale that may run on any computer. The user is charged on a unit basis. The secure processes described for the system microprocessor will have applications in other secure processes.

1 **TITLE OF INVENTION:**

2 **A SECURE PAY-AS-YOU-USE SYSTEM FOR COMPUTER SOFTWARE**

3

4 **TECHNICAL FIELD:**

5 The distribution of software and other information reversibly functionally limited, usually by encryption, requiring
6 reversal by a secure device that may also be used to provide software on a pay-as-you-use basis.

7

8 **BACKGROUND TO THE INVENTION AND DESCRIPTION OF THE RELATED ART:**

9 The invention describes a method and apparatus that protects software objects. The protected information cannot be
10 used without the assistance of one or multiple secret processing devices. Said *secret processing devices* provide a
11 mechanism for reversing the protection applied to said *information* and said *reversing* may only be activated by
12 certain predetermined secure processes. The process of activating said *reversing* usually ensures that the producer of
13 said *information* and or their agents receive correct payment for usage.

14

15 High speed dispersal of information between most computers with access to a modem/telephone line, together with
16 forthcoming means of storing in excess of ten gigabytes of information on a writable optical disk, is likely to lessen
17 the commercial value of information released in clear code format. One clear code copy in the wrong hands could
18 result in its effective worldwide dispersal in a short time.

19

20 One objective of the invention is to provide a means of maintaining security applied to information during and after
21 it performs the functions required of it.

22

23 The known art describes a means of protecting computer software by requiring the presence of particular devices to
24 operate properly. These devices are secure to varying extents. The problem with computer software is that the
25 protection applied must be reversed prior to providing the information to the system CPU for processing. Once
26 reversed it is accessible to those experienced in the art.

27

28 Known art WO 90/13865 describes a process whereby a secure location remote to a potential user supplies an
29 encrypted software object to a user controlled data processing system and a secure method of decrypting said
30 encrypted software object. The software object usually contains information that is continually varying. This
31 provides security by default in that it is a waste of time analysing information that is redundant shortly after its
32 creation. This known art does not provide effective security against objects that, once downloaded and deciphered,
33 may be used in perpetuity as is usually the case with computer programs.

34

35 Known art described in AU-A-14856/95 relies on software methods to process the deciphering algorithms used to
36 reverse functional limitations placed on software objects. Said software methods are susceptible to an experienced
37 person generating usable information from protected software objects reliant on this method.

38

1 The current invention may be used to significantly strengthen the security and flexibility of the known art described
2 in WO 90/13865 and or AU-A-14856/95. It may also be used as a significantly more secure and flexible
3 replacement for this known art.

4

5 Other known art calculates (and this may be by the use of information supplied by an associated computer program)
6 certain values in a secure environment. Said values are passed to an associated computer program and compared
7 with internally generated values. These methods are in effect verifying that said secure environment is present and
8 has presumably been purchased with the computer program. Said secure environment is not providing an essential
9 function absent from said associated computer program, as it is practical to circumvent this protection by
10 disassembly of parts of the program to examine the other side of the equation.

11

12 The known art describes a cryptoprocessor (US patents 4465901, 4419079, 4278837, 4168396) that is capable of
13 deciphering instructions and or data in realtime as it is loaded into the central processing unit. Said instructions and
14 or data are usually stored in enciphered format in external memory. This known art is not suitable for use in a user
15 controlled data processing system:

- 16 • that may variably have one or multiple programs loaded from a potentially large selection and or said programs
17 may use different decryption parameters; and or
- 18 • where the address occupied by a particular program may be different on each occasion it is loaded (said known
19 art is particularly directed at ensuring that an encrypted program will crash with minor variations to its location
20 in the address map); and or
- 21 • where one or multiple encrypted programs may need to co-exist with clear code programs in a constantly
22 varying environment; and or
- 23 • where it is not usually practical to protect the external memory from tampering and or analysis; and or
- 24 • where an interrupt to an encrypted program may direct processing to non-secure methods that may threaten the
25 secrecy of certain information and this may include that within CPU registers at the time of interrupt; and or
- 26 • where an encrypted program needs to temporarily transfer processing to an unsecure location; and or
- 27 • where an encrypted program needs to protect its stack from analysis; and or
- 28 • where an encrypted program exists as multiple modules that are loaded as required and where one or multiple
29 modules may use different decryption parameters that need to be dynamically changed as program execution
30 flows between them; and or
- 31 • where different programs in a multitasking environment, that may have different decryption parameters, need to
32 be securely switched on a frequent basis.

33

34 The known art describes the programming of software objects into a secure microcontroller. This is restricted to a
35 limited number of predefined functions. However, the known art does not describe the processing of software objects
36 within a user controlled data processing system in conjunction with a secure environment, that is not practical to
37 analyse, wherein said secure environment (that may be a microprocessor) includes inaccessible information and also
38 provides for external software objects, that may be selected and loaded as required from a potentially large number,
39 to be able to transfer processing (and or pass any required data) to said inaccessible information within said secure

1 environment, wherein said secure environment includes computer instructions and or data (including that passed)
2 which may be processed in secret within said secure environment to perform important functions and or any other
3 functions that are absent from said software object and that provides for transfer of processing and or data back to
4 said software object as appropriate; and or provide data that is absent from an external software object when
5 appropriately requested by said software object. Said inaccessible information:

- 6 • may be preprogrammed into a storage device; and or
- 7 • may be greater than the available storage device within said secure environment; and or
- 8 • may be dynamically swapped in and out of said secure environment; and or
- 9 may be transferred to said secure environment and decrypted within said environment and processed within said
10 secure environment; and this applies for any of the preceding combinations when said secure environment is part of:
 - 11 • one or multiple system microprocessors, and or
 - 12 • one or multiple devices attached directly and or indirectly to the user controlled data processing system, and or
 - 13 • within devices linked via network and or Internet (or equivalent in part or whole).

14

15 The known art does not describe any method and apparatus that permits multiple protected software objects,
16 including those protected:

- 17 • by software encryption/decryption alone, and or
- 18 • by secure decryption within a secret environment, and or
- 19 • by secure decryption and secure execution of the ensuing decrypted information within a secret environment,
20 that allows said multiple protected software objects to concurrently and or otherwise execute in a multitasking and
21 or multiuser and or multiprocessor environment (where said multiprocessors may be the same and or different).

22

23 One objective of the present invention is to provide a method and apparatus:

- 24 • that overcomes part or all of the aforementioned deficiencies in the known art, and
- 25 • that may be used to support a multiplicity of new methods and apparatus for distributing computer software,
26 and
- 27 • that may be used to strengthen a number of weaknesses with the current art.

28

29 The known art describes a number of methods for distributing software whereby the user pays on 'an as used basis'.
30 These methods include those protected exclusively by software methods. These usually include various software
31 clocks that count down on a predetermined basis, and inactivate the program at the appropriate time. Payment is
32 usually made for the use of a particular object on the terms predetermined. Disadvantage of this method include:

- 33 • inherent lack of security;
- 34 • the unsecure nature of the protection processes make it unlikely that software vendors will feel comfortable with
35 the process;
- 36 • should software vendors make a large selection of software available, users would usually be required to pay for
37 access to the full period predetermined for each program, making it unappealing for users to access a large
38 number of different programs as required (apart from any trial periods);
- 39 • lack of flexibility;

1 • user cannot self determine the amount of time required and pay accordingly.

2

3 The security of the process for renting software is improved with known art described in WO 90/13865, wherein
4 there is a secure device within the user controlled data processing system that monitors the time used by a software
5 object downloaded from a service provider. Details of time used is periodically transferred back to the service
6 provider. This method requires the user to be on line to receive said software object and to receive the timing
7 parameters pertaining to said software object. The method also requires the user to remain on line for continued
8 security of the process and to periodically upload elapsed time to the service provider. The user would normally be
9 billed on a predetermined basis for software usage.

10

11 The known art does not describe a method and apparatus to provide a secure and secret environment for the secure
12 recording of usage of more than one program at a time in a multitasking and or multiuser and or multiprocessor
13 environment.

14

15 The known art does not describe a secure and secret environment that can be securely preprogrammed with a
16 predetermined amount of usage, whereby said usage:

17 • is prepaid and or

18 • is a credit limit for use that will be billed at a later date;

19 and

20 said predetermined amount of usage remains available for an extended period of time (preferably surviving loss of
21 system power) for use as required, with said predetermined amount of usage appropriately varied according to use of
22 multiple software objects over said extended time, and or

23 said predetermined amount of usage may be securely updated with additional usage rights as required.

24

25 The known art does not describe a secure and secret environment that can:

26 securely record usage of software objects; and or

27 securely maintain a record of amounts owing to different vendors and or against different software objects, and or

28 provide a report on any basis, including usage, and or

29 temporarily or permanently disable itself in part or whole should said predetermined amount of usage be utilised,

30 and or

31 temporarily or permanently disable itself should it fail to receive secure confirmation that reports sent to a service

32 provider have been received.

33

34 The known art does not describe a method and apparatus to permit a large number of software objects to be created
35 that include information about their particular billing requirements, whereby said software objects are subsequently
36 distributed on a large scale permitting each potential user to use any of the software objects as frequently as they
37 require and only pay for use incurred, said use reducing the amount of usage predetermined within said secure and
38 secret environment. There is no known method and apparatus that compensates for variations between information
39 stored within previously released software objects and that which is current, particularly as it applies to billing
40 information.

1
2 It is another objective of the invention to provide a method and apparatus to overcome, in part or whole, the
3 aforementioned deficiencies with the known art, and said method and apparatus may also be used for a number of
4 other described applications. An important objective is the provision of a secure, virtually transparent (to the user)
5 method of renting software for use on a user controlled data processing system (UCDPS), on a usage basis, that in
6 one configuration is independent of any attachment to any devices coupled remotely (eg. telecommunications link) to
7 the UCDPS.

8
9 The method and apparatus described to advance the art of protecting and distributing computer software may also be
10 adapted in part or whole to the protection and distribution of other commercially valuable information.

11
12 **DEFINITIONS:**

13
14 Replication or duplication may be one to many copies and may include replication of part or whole in any
15 combination and or number.

16
17 decrypt(ed) and decipher(ed) may be used interchangeably and refer to reversal of a previously applied encryption
18 process. Unless relating to a specific decryption process that is a claim of the invention it may be interpreted as
19 being any known method of decryption.

20
21 Decode is generally used in the traditional computer sense of decoding addresses etc, however, where the context
22 permits it should be interpreted as for decrypted..

23
24 Clear text (or clear code) is information that is not encrypted and may be derived from encrypted information and
25 or may have been supplied in as clear code.

26
27 Internal to the System CPU (or System Microprocessor) indicates that the hardware and or microcode and or
28 software is on the same integrated circuit substrate; and or that they are on multiple substrates interfacing where
29 necessary using any known method and apparatus within the package of the system CPU; and or part of the device
30 is within the system CPU package and part (or all) external to the System CPU package and attached externally to
31 the System CPU package using any method and apparatus.

32
33 A system CPU also referenced as system microprocessor, is one that a person experienced in the art would
34 consider to be suitable as the primary (or one of multiple primary) processing units in a User Controlled Data
35 Processing System (UCDPS).

36
37 Processing or process refers to the actual execution of computer instructions and or the manipulation (in any way)
38 of data associated with the computer instructions and or manipulation (in any way) of any other data.

39

1 Software Object: A software object is that which a person experienced in the art would consider a software object.
2 Computer programs and or subroutines that constitute part of a computer program are considered software objects.
3 Data pertaining to said computer programs is a software object. Information that is processed by a UCDPS and
4 subsequently displayed as text and or images and or sound for any reason, including as normal output from a
5 computer program and or electronic books (and similar) and or music and or other sound and or visual imagery and
6 or video in the form of motion pictures is a software object.

7

8 PCPU: Within this application reference to a PCPU or Protected CPU refers to Secret Processing Device (SPD)
9 embedded within the system microprocessor package of a UCDPS.

10

11 ESPD: Reference to an External Secret Processing Device or ESSPD refers to an SPD attached directly or indirectly
12 to any other part of the UCDPS.

13

14 End of Definitions.

15

16 DESCRIPTION OF THE DRAWINGS:

17 Figure 1 is a diagram of an apparatus suitable for use as a secret processing device embedded within the system
18 microprocessor.

19 Figure 2 is a diagram of basic embodiment of an SPD for use external to the system microprocessor.

20 Figure 3 is a diagram of the address map for secure functions within the system microprocessor.

21 Figure 4 is a diagram of command port structure.

22

23 DESCRIPTION OF THE INVENTION:

24

25 A SECURE PAY-AS-YOU-USE SYSTEM FOR COMPUTER SOFTWARE

26 The invention describes a method and apparatus for the protection of software against piracy and provides a secure
27 process for the mass distribution of software. This is done by functionally limiting a software object and securely
28 linking it with conditions of use and object support information to create a Protected Software Object (or PSO)
29 which must be used with a Secret Processing Device (or SPD) that is directly or indirectly attached to a User
30 Controlled Data Processing System (or UCDPS). This provides a flexible and novel method of using and paying for
31 software. The preferred location of the secret processing device is within the package of the system microprocessor
32 of the User Controlled Data Processing System where the combination is referred to as a Protected CPU (or PCPU).
33 The following describes those aspects considered essential to a full implementation of the invention.

34 1) a method of distributing software objects from a producer to a potential user comprising the method steps of:

35 i) providing a secret processing device (or SPD) for direct and or indirect attachment to a UCDPS whereby said SPD
36 is any one or multiple hardware devices that may use any combination of software and or microcode and or any
37 other method to provide a secure and secret environment for processing information and or storing information and
38 that provides the following:

39 a) any one or multiple methods and or apparatus that:

- 1 securely decrypt and execute instructions and or securely decrypt and process data that complies with part or all of
2 the requirements of reversing functional limitations applied using the Oscar method (described later); and or
3 reverses the functional limitations applied using the Groover method (described later); and or reverses any other
4 functional limitations applying to a PSO; and or transfer into the SPD any part of one or multiple PSOs into the SPD
5 that may be necessary to provide any of the functions required by said PSOs; and or access any part of one or
6 multiple PSOs that may be located external to the SPD in order to provide any of the functions required by said
7 PSOs; and or examine the generic and or distinct conditions of use linked to a particular PSO, and or determine a
8 response to said conditions of use; and or respond to said conditions of use;
9 and or
- 10 b) may be embedded, in part or whole, within the package of the system microprocessor of the UCDPS; and or may
11 be within any one or multiple devices attached directly and or indirectly to the system microprocessor and or the
12 UCDPS, and may not disrupt the normal functions of the UCDPS and may in part or whole be used as part of an
13 application that in part or whole is dependent on connection to a distributed data processing system, that may be of
14 any type, including local networks and or intranet (or similar) and or the Internet (or similar), and may benefit from
15 connection to one or multiple remote computers and or any other devices to simplify transmission of various
16 information, however, said secure and secret processing functions, in part or whole, are functional and or remain
17 functional, when said UCDPS that has been provided with said secure and secret processing functions, is used as a
18 standalone unit independently of attachment to remote devices, and said UCDPS may be switched on and off for
19 variable periods of time and or moved to different locations and or reset as frequently as required, without affecting
20 the functions that are provided to said UCDPS;
21 and or
- 22 c) provides an area of secure memory storage devices that is not practical to analyse;
23 and or
- 24 d) provides for partition of secure memory storage devices into one or multiple secure system partitions and one or
25 multiple user partitions whereby programs in system partitions may access user partitions, however, a user partition
26 may not access a system partition unless authorised, and or any particular user partition may not access any other
27 user partition unless authorised;
28 and or
- 29 e) may transfer part or all of protected software objects and or any other software object from unsecure to secure
30 locations for processing and or transfer information from a secure location to an unsecure location; and or
- 31 f) may securely decrypt part or all of decrypted parts of protected software objects and or any other encrypted
32 information within said secure locations;
33 and or
- 34 g) may process part or all of one or multiple protected software objects in secrecy, including processing of part or all
35 of that information loaded in encrypted format and decrypted;
36 and or
- 37 h) are programs and or data preprogrammed into the device and or transferred in encrypted format and or in clear
38 code, that assist and or replace any other known software protection and or distribution systems that are dependent
39 in part or whole on user accessible software processes and or unsecure identifying codes to provide protection
40 against unauthorised use of software objects, when part or all of said user accessible software processes and or

- 1 unsecure identifying codes are transferred (either by preprogramming and or dynamically as required) to a secure
2 location that permits private processing of the information;
3 and or
4 i) have the capacity to detect whether part or all of said suitably configured protected software objects have been
5 tampered with;
6 and or;
7 j) may perform secret encryption and or secret decryption in a manner that cannot be analysed, and this may be a
8 software and or hardware function;
9 and or
10 k) have the capacity to implement in part or whole, one or multiple hardware devices in programmable logic,
11 preferably programmable logic that may be rapidly erased in the event of tampering, and this includes encryption
12 and or decryption functions implemented in part or whole in hardware, and hardware functions implemented in
13 programmable logic may be dynamically programmed by one or multiple protected software objects;
14 and or
15 l) may use any method to determine that there is an attempt to gain access to secret information within the SPD, and
16 said attempt may be physical and or logical analysis, and the response may be any action, using any method,
17 including disabling, temporarily and or permanently, part or all of the SPD and or invalidating in any way part or all
18 of the secret information that may be stored within secure memory storage devices;
19 and or
20 m) may securely store information in encrypted and or clear code format in locations inaccessible to unauthorised
21 parties and or securely store information in encrypted format in locations that may be accessible to unauthorised
22 parties, and may detect tampering with stored information;
23 and or
24 n) may have the capacity to securely monitor the usage of protected software objects;
25 and or
26 o) may securely record the usage of said protected software objects and the record may include a secure breakdown
27 of the usage on a producer and or product and or any other basis, and said record in part or whole is non-volatile;
28 and or
29 p) may request and or compel (this may include temporarily or permanently disabling part at least of the SPD) the
30 user of the UCDPS to provide any necessary reports of usage to a service provider and or to any other location;
31 and or
32 q) may confirm that said reports have been received as required;
33 and or
34 r) does not require modification of the User Controlled Data Processing System operating system;
35 and or
36 s) may not require special routines to intercept calls to said system operating system;
37 and or
38 t) may identify the type of protected software object and act as required;
39 and or
40 u) provides or have access to one or multiple tamperproof, non-volatile source of time and or date;

- 1 and or
- 2 v) provides or have access to one or multiple tamperproof timers;
- 3 and or
- 4 w) provides one or multiple methods of identifying at least one tamperproof environment, this may include the use of
- 5 an electronic signature;
- 6 and or
- 7 x) provides one or multiple secret codes and or programs that are unique to a particular SPD and or that are common
- 8 across particular groups of SPDs;
- 9 and or
- 10 y) provides one or multiple programs, that may be preprogrammed (into the SPD) and or transferred (into the SPD)
- 11 as required, that use secret information unique to the SPD to decrypt software objects;
- 12 and or
- 13 z) may process multiple protected software objects in a multitasking environment, this may be transparent to the
- 14 UCDPS operating system;
- 15 and or
- 16 aa) include functions, preferably implemented in reprogrammable secure memory, that may be edited and or
- 17 modified and or deleted and or expanded and or in any other way altered, in a secure manner and usually
- 18 transparently to the user of the UCDPS, enabling appropriately configured PSO(s) to adapt the secure information in
- 19 the SPD for any purpose, including: making multiple SPDs identical in part at least (including multiple PCPUs in a
- 20 multiprocessor system); and or create one or multiple applications not currently available to the SPD; and or that
- 21 permits any current application to be dynamically adapted, including dynamically reprogramming various hardware
- 22 functions implemented in part or whole with reprogrammable logic connections; and or dynamically modifying
- 23 decryption processes;
- 24 and or
- 25 ab) are programs and or data preprogrammed into the device and or transferred in encrypted format and or in clear
- 26 code that assist any function described for the correct processing of protected software objects;
- 27 and or
- 28 ac) include secure memory that stores various internal system routines and may be loaded with externally supplied
- 29 objects for decryption and or execution and or any other purpose;
- 30 and or
- 31 ad) may decide to reverse one or multiple functional limitations on one or multiple PSOs based on said conditions of
- 32 use, where said decide is in part at least autonomous to the SPD and based in part at least, on secure processing
- 33 internal and or external to the SPD of generic information applicable to multiple PSOs, that may include a plurality
- 34 of any information states within and or external to the SPD, including one or multiple electronic credits that is
- 35 modified (directly or indirectly) in response to use of PSOs on time and or events used and or any other basis, and as
- 36 long as the requirements of one or multiple PSOs and or SPDs are complied with, the user of said UCDPS may be
- 37 able to execute and or process one or multiple PSOs on the same basis as if they were unprotected software objects;
- 38
- 39 ii) providing a software object;
- 40

1 iii) modifying part or all of said software object such that it is functionally limited to run on only a UC DPS fitted
2 with a SPD and or equivalent and the functional limitation is by the Oscar method as defined below and or by the
3 Groover method as defined below and or by any other method and said functional limitation may be of one or
4 multiple essential parts of the software object, preferably such that it is not practical to regenerate the original
5 software object from any parts that are not functionally limited, and said modifying is preferably done at a secure
6 location (also referenced as a service provider) that has access to part or all of secret information contained within
7 the SPD and for any particular functionally limited software object the functional limitation may only be reversed on
8 a specific SPD with any unique characteristics necessary to reverse the functional limitation, or the functional
9 limitation may be reversed on a plurality of SPDs characterised by common characteristics necessary to reverse the
10 functional limitation; and or
11
12 modifying part or all of said software object, using any method, such that it is securely linked in part or whole, using
13 any method, to one or multiple conditions of use, also referenced as PCPU Inclusion Commands (or PIC), that in
14 part or whole are tamperproof and that include any code that directly or indirectly identifies the producer of the
15 software object and or identifies the software object such that when an SPD interacts with the software object it may
16 record use of that particular software object and or use of PSOs by a particular producer and or use on any other
17 basis, in part or whole, where the record of use in part or whole is used in determining remuneration to the producer
18 and or any other parties; and or the conditions of use include any code that contains information which may be used
19 by the SPD to determine if the software object:
20
21 is permitted to execute in part or whole on a units of time used basis, and if permitted, what fee should be applied
22 for the use of the software object and said fee may be any unit of measurement and is preferably a generic units of
23 use basis and said generic units may be attributed any real currency value at any stage;
24 and or
25 is permitted to execute in part or whole on an events occurring basis, for example the number of times one or
26 multiple parts of the program are loaded and or executed and or any other measurable events basis, and if permitted,
27 what fee should be applied for the use of the software object and said fee may be any unit of measurement and is
28 preferably a generic units of use basis and said generic units may be attributed any real currency value at any stage;
29 and or
30 is permitted to execute on an unlimited basis subject to a fee, and if permitted, what fee should be applied for the use
31 of the software object and said fee may be any unit of measurement and is preferably a generic units of use basis and
32 said generic units may be attributed any real currency value at any stage;
33 and or
34 is permitted to execute on any type of limited basis subject to a fee, and if permitted, what fee should be applied for
35 the use of the software object and said fee may be any unit of measurement and is preferably a generic units of use
36 basis and said generic units may be attributed any real currency value at any stage;
37 and or
38 requires entry of one or multiple data keys of any type prior to initiating use of part or all of the software object for
39 the first and or any other time on a particular SPD and may include whether or not a fee is to be charged for
40 providing the data key;

- 1 and or
- 2 requires any other restrictions to be placed on use;
- 3 and
- 4 any software object modified in part or whole as described is referred to as a Protected Software Object (or PSO);
- 5 said Oscar method, is any functional limitation of part or all of a software object by any method of encryption,
- 6 usually at a secure location remote to the user, where part or all of the reversal of the encrypted information, by
- 7 decryption and or any other method, occurs within a secure environment directly and or indirectly attached to a
- 8 UCDPS such that part or all of the instructions and or data of the software object reconstituted by said reversal are
- 9 not accessible to analysis by any unauthorised party and the execution of part or all of said instructions and or the
- 10 processing (using any method) of part or all of said data that is not accessible to analysis by an unauthorised party
- 11 remains in part or whole inaccessible to analysis by any unauthorised party. The result is that part at least of the
- 12 functional limitation placed on a software object is not compromised by the process of using said software object;
- 13 said Groover method is any functional limitation of part or all of a software object by deletion of part or all of the
- 14 information within the software object, usually at a secure location remote to the user, where part or all of the
- 15 reversal of the deletion, by any method, occurs within a secure environment directly and or indirectly attached to a
- 16 UCDPS such that part or all of the instructions and or data of the software object reconstituted by said reversal are
- 17 not accessible to analysis by any unauthorised party and the execution of part or all of said instructions and or the
- 18 processing (using any method) of part or all of said data that is not accessible to analysis by an unauthorised party
- 19 remains in part or whole inaccessible to analysis by any unauthorised party. The result is that part at least of the
- 20 functional limitation placed on a software object is not compromised by the process of using said software object;
- 21
- 22 iv) providing one or multiple PSOs onto computer-accessible memory media and or any suitable apparatus for
- 23 electronically transferring said PSOs to a potential user, and preferably the conditions of use attached to said one or
- 24 multiple PSOs permit said PSOs to be used on a time or events used basis in a UCDPS suitably equipped with a
- 25 SPD that has sufficient aforementioned units of measurement stored within and or securely accessible;
- 26
- 27 v) shipping said one or multiple PSOs on computer-accessible memory media to a potential user and or
- 28 electronically transferring said one or multiple PSOs;
- 29
- 30 vi) loading said one or multiple PSOs into a UCDPS and executing as permitted by conditions of use;
- 31
- 32 vii) where required by the conditions of use or any other reason, a means for the user to:
- 33 • request the supply of one or multiple units of measurement that may be required by the SPD for any purpose,
- 34 and or
- 35 • receive one or multiple said units of measurement, preferably in suitably encrypted format, that may use any
- 36 method, and transfer said units of measurement into the SPD, and or accessible to the SPD, and or
- 37 • request the supply of one or multiple data keys that may be required by the SPD, and or
- 38 • receive one or multiple data keys and transfer said data keys into the SPD, and or accessible to the SPD, using
- 39 any method, and or

- 1 • generate one or multiple reports of software usage and or any other information that may be required, and
- 2 supply said reports to service provider and or any other external location, as required, and or
- 3 • receive one or multiple codes confirming that said report has been received and supply said one or multiple
- 4 codes confirming into the SPD and or accessible to the SPD, and or
- 5 • request the service provider and or any other authorised party for one or multiple codes that may be used to
- 6 reactivate part or all of the SPD that may have been disabled for any reason
- 7 • receive one or multiple codes to reactivate part or all of the SPD that may have been disabled for any reason and
- 8 transfer said codes into the SPD, and or accessible to the SPD and
- 9 for any of the preceding, the information generated by the UCDPS and or received from the service provider is
- 10 preferably transferred electronically, however, any other combination of methods may be used including mailing of
- 11 computer-accessible memory media containing the information.

12

13

14 **PREFERRED IMPLEMENTATION OF THE INVENTION:**

15 To assist with understanding the invention, reference will now be made to the accompanying drawings which show
16 one example of the invention. In the drawings, Figure 1 shows an apparatus that is suitable for use as a secret
17 processing device embedded within the system microprocessor.

18

19 Throughout this description and the accompanying drawings, many signal lines are represented by a single line and
20 an identifying symbol. This may represent any number of signals, for example, a certain logic function output may
21 clock, clear and set a flip flop, however, usually only one signal line will be shown to represent all three. In the case
22 of various buses, the lines represent whatever number of signals constitute said bus or whatever subset of said bus is
23 relevant for the logic functions it may be entering or leaving. Many control lines are not described or shown in this
24 description as it will be obvious to anyone experienced in the art, where, when, and how, they should be used in
25 order to make functional any apparatus described; descriptions are detailed when needed to help clarify the
26 implementation of any particular function. Throughout this description, the polarity of signals is usually immaterial
27 and not discussed unless of specific consequence; it will be whatever is required in a practical implementation of the
28 invention. When a latch or other device is set or cleared the alternative arrangement is allowed for. While a latch or
29 register is a commonly used storage device in parts of this description, it may be replaced with any other logic and or
30 combination of logic and or software and or microcode that results in a similar outcome.

31 The invention describes:

- 32 1. a method of reversibly functionally limiting a software object that requires a secret processing device (or SPD) to
- 33 reverse part or all of the functions of the reversible functional limitations and preferably includes a method of
- 34 securely linking the conditions of use that apply to a particular reversibly functionally limited software object to said
- 35 reversibly functionally limited software object such that this information may be used in part or whole to determine
- 36 whether to permit the SPD to reverse the reversibly functionally limited software object. The conditions of use are
- 37 preferably an integral part of the reversibly functionally limited software object and or supplied as one or multiple
- 38 other modules that are linked in a manner that prevents the unauthorised separation of conditions of use and
- 39 reversibly functionally limited software object. This produces a protected software object (or PSO) which may be
- 40 distributed to a potential user and loaded onto a UCDPS and includes instructions to the SPD on how it may be

1 distributed to a potential user and loaded onto a UCDPS and includes instructions to the SPD on how it may be
2 used. This permits objects to be widely distributed and used on stand alone UCDPSs conditional on the SPD that is
3 required to reverse, in part at least, the reversible functional limitations, complying with the conditions of use. The
4 conditions of use may also be supplied in any other way, e.g. as separate modules and may be loaded, or otherwise
5 linked, into an SPD transparently to the operating system of the UCDPS or by using said operating system.

6
7 When a PSO is securely linked with conditions of use it may be used on a UCDPS equipped with an SPD without
8 any extra intervention by the user than would normally be required for the protected object in its native software
9 object form, with the exception of any requirements that the SPD requires of the user.

10
11 2. an apparatus referenced as an SPD that has various secure system functions that allow it to interact correctly with
12 one or multiple reversibly functionally limited software object prepared for use with one or multiple SPDs. The SPD
13 includes an internal secure and secret operating system referred to as secure system functions. They interact in any
14 way required to appropriately reverse in part or whole, reversibly functionally limited software objects. The secure
15 functions of the SPD may have other applications.

16
17 The preferred embodiment of an SPD is included within the package of the system microprocessor; such a
18 combination may be referred to as a protected CPU (or PCPU). An SPD may be directly and or indirectly attached to
19 the UCDPS external to the package of the system microprocessor; this is referenced as an ESPD. A PCPU may
20 include multiple system microprocessors. There may be multiple PCPUs within a UCDPS. There may be multiple
21 ESPDs within a UCDPS. Multiple SPDs in any location may interact in any way and combination with any others
22 or not at all. The embodiment of a system microprocessor to implement the apparatus of the invention is
23 predominantly dependent on the use of secure memory storage devices of various types and an ability to securely
24 process information within these devices and a person experienced in the art will be able to arrange logic, software
25 and microcode in many combinations to effect versions of an SPD and PSO that are within the spirit of the
26 invention. This arrangement permits the secure functions required of the present invention to be implemented. A
27 person knowledgeable in the art will appreciate that the secure processes used for the invention may have multiple
28 other secure applications. The known art does not describe a system microprocessor suitable for use in a UCDPS
29 that provides the secure processing functions described in this embodiment. The invention allows for any system
30 microprocessor that provides the apparatus and or functions described in the application.

31
32 Figure 1 shows a block diagram of a system microprocessor that may communicate with a secure microprocessor
33 that is securely linked to one or multiple secure functions, including secure memory, secure realtime clock and other
34 secure functions. When the secure memory is programmed with appropriate information, the combination of
35 software routines and embedded hardware functions and changes to the microcode of the system microprocessor
36 provides all of the requirements of an SPD securely embedded within the system microprocessor package. This
37 device may be used to replace the existing system microprocessor in a UCDPS and, subject to being supplied with
38 any information required to meet the conditions of use attached to a PSO, may execute that PSO as if it were a
39 normal software object. It will be appreciated by those experienced in the art that there are many ways of combining
40 logic, software and microcode to implement the device as described.

1
2 Figure 1 shows the silicon chip 130 of the system microprocessor 1. The system microprocessor 1 normally
3 interfaces with external locations via an address bus 5 and address buffers 2 and data bus 6 and data buffers 3 and
4 various control logic 7 via buffers 4. Buffers 2, 3 and 4 are enabled/disabled during normal processing by system
5 microprocessor 1 via control line 9. Instructions are interpreted and implemented by a combination of microcode
6 and logical devices within the instruction execution block 8, located within system microprocessor 1. The apparatus
7 of the invention needs to communicate with the system microprocessor 1 and this is most readily implemented with
8 dual port memory 19, a memory that allows read and write accesses by two devices to the same addresses on an
9 asynchronous basis. There are many ways of achieving an equivalent result. As described in this embodiment the
10 DP memory 19 is not intended to store secure information; it is functioning as a port between unsecure and secure
11 processes and it is not practical for an unauthorised person to access secure information without very complex codes.
12 The invention allows for the recording of failed attempts at access and may disable itself to prevent repeated
13 attempts to compromise secure elements.
14
15 The system microprocessor side of the DP memory 90 may be decoded into the normal address space of the UCDPS,
16 using any known decoding apparatus, however, the preferred method is to make the addresses occupied by the 90
17 side of the dual port memory 19 a separate address space to the UCDPS. This is done by providing an instruction,
18 referenced as a transparent address activator or TAA, that, depending on the attached opcode, performs a number of
19 functions.
20
21 The primary interaction of the system microprocessor 1 to dual port memory 19 will be to read and write data
22 between UCDPS addresses and dual port memory 19 for transfer into secure functions 50 by the secure
23 microprocessor 20 and the reverse. There may also be a requirement to transfer data from one location to another
24 within the dual port memory 19. The address space occupied by the dual port memory may be any practical amount.
25 Reset of the system microprocessor 1 initialises normal address decoding, with the dual port memory 19
26 inaccessible by the system microprocessor 1.
27
28 The execution of a TAA instruction, with for example X as the opcode, and the combination referenced as TAAX, is
29 carried out if the system microprocessor 1 wants to move information from UCDPS memory to dual port memory
30 19, in which case buffers 2, 3, 4 would be activated by 9 for reads from any address in the UCDPS memory. During
31 a write operation the address decoder enable signal 11 is active, enabling the address decoder 10 to decode a
32 predetermined address block (that may be made programmable) of dual port memory 19 using chip select 13, that
33 also keeps the buffers 2, 3, 4 disabled by blocking any enabling effect of 9 via logic gate 14. Data is read from
34 UCDPS memory space and written to dual port memory 19. Instruction TAAY performs the reverse by activating 11
35 during read operations. Instruction TAAZ activates 11 for reading and writing. TAAB disables 11 for all reading
36 and writing, the normal situation. The TAA instruction only affects operations that are fetching data, not
37 instructions, and most system microprocessors have a signal to distinguish between the two. An instruction
38 referenced as the TBAX instruction may be used to activate instruction fetches from dual port memory 19, by
39 activating 11 during instruction fetches and may be disabled by the TBAY instruction. Instructions are read
40 operations. TAA and TBA instructions may be used in any combination. A reset has the same effect as TAAB &

1 TBAY, ensuring normal processing on startup. While TBAX is active, instruction fetches from addresses outside the
2 dual port memory 19 are from UCDPS memory. A watchdog counter or timer may be set, and this may be automatic
3 to perform an automatic TBAY instruction or any other method to avoid trapping the system microprocessor in dual
4 port memory 19.

5

6 This method and apparatus provides a novel transparent method of including one or multiple devices within a
7 system microprocessor without potentially conflicting with existing resources in a UCDPS and has multiple
8 applications to the art of system microprocessor design. To avoid problems with interrupts directing processing to
9 another routine that expects a normal environment, interrupts are inhibited by TAA and TBA instruction. An
10 alternative allows for similar instructions that do not inhibit interrupts, allowing the interrupt handler and or task
11 switcher to handle the situation, in which case the TAA and TAB instructions are disabled by an interrupt and a
12 record of their status is stored in a location, eg. a special register, accessible by the system operating system.

13

14 Secure processing is provided by including a second microprocessor 20 within 130 that may read and write to
15 addresses within the secure address map 50 without being available to external analysis. Secure address block 50 is
16 predominantly memory, divided into a small amount of mask ROM 51 to initially program the other information
17 into the device, flash memory 52 for storage of information that needs to remain in the device in the event of total
18 power loss, and battery backed static memory 53, that stores important information which may be rapidly erased in
19 the event of tampering. The microprocessor 20 communicates with the secure memory 50 via address lines 84, data
20 lines 100, and other various control lines including read write 93. Also decoded within the secure memory address is
21 a battery backed realtime clock and or calendar 89 that cannot be tampered with and a crystal. A data encryption
22 standard engine is preferably included. Decoding of secure addresses is provided by decode logic 25 and the various
23 chip select signal are output on 83 to the various secure devices. The power management logic 65 receives external
24 power on 60 and battery power on 87 from (preferably rechargeable) battery 70. An A/D converter 75 monitors
25 voltage. Continuous power is supplied to 50 via 87. Power management 65 may also be used for any additional
26 voltages to flash memory 52, other battery backed logic and provides recharging power to the internal battery 70.
27 The microprocessor 20 communicates with the system microprocessor 1 via a dual port memory 19. The
28 microprocessor 20 side 91 of dual port memory 19 is decoded by 25 via 40. Data lines 22, address lines 21 and read
29 write 23 connect with 19 to allow reads and writes of information between microprocessor 20 and dual port memory
30 19. A similar method allows the system microprocessor to communicate with dual port memory via chip select 13
31 from its decode logic 10 and address lines 14 and data 6. The decode circuit 10 uses high order address lines 12 and
32 control lines 32 (e.g. valid address) and 11 (activated by TAA, TBA). This provides a method of transferring
33 information to and from external locations to dual port memory 19 that may be read and written by microprocessor
34 20. No user supplied program can access the information in secure memory without access to the secret codes
35 required, and these may be made as complex as secure memory resources allow.

36

37 It is preferable that the secure microprocessor includes a direct memory access (DMA) facility to move blocks of
38 information from UCDPS memory directly into secure memory locations and or from secure memory to external
39 locations. This may actually improve the efficiency of the original system microprocessor, permitting it to perform
40 other tasks while a block of information is securely processed in internal memory. Access to this DMA facility

1 should be decoded into the secure function address block and should only be able to be selected by an instruction
2 originating within secure system functions (as described later). Any possibility of an external program and or a
3 program executing in a user partition having unsupervised access to the DMA controller 125 that may be
4 programmed to move a large block of system information to external locations would be disastrous.

5
6 The microprocessor 20 would usually program the DMA controller 125 via data bus 100 and chip select 142 and
7 read/write 102, using a routine known to have originated within one or multiple predetermined system functions.
8 The details of including a DMA controller 125 are not described or shown. The method involves multiplexing the
9 address 5, data 6 and control lines 7 of the system microprocessor 1, with similar signals generated by the DMA
10 controller 125 to read or write external locations and multiplexing of the address, data, and control lines of
11 microprocessor 20 to read and write secure addresses. These methods are known to the art and, because the DMA
12 controller is within the system microprocessor chip, arbitration logic between system microprocessor 1 and DMA
13 controller 125 would be easier to implement at a logical level than for external DMA controllers. This type of DMA
14 is transparent to external devices.

15
16 The invention also allows that the microprocessor 20 may be a duplicate of the system microprocessor 1 providing a
17 very powerful processing system, allowing secure and unsecure execution to proceed concurrently. Another
18 attractive option is to use two different system microprocessors e.g. an Intel type of CPU and a Motorola type of
19 CPU. These may be multiplexed by one experienced in the art such that one system microprocessor performs normal
20 system functions while the other provides secret processing of various functions. An electronic switch, that may be
21 activated in any way, eg. hold reset low, may switch the roles. The secure functions may be duplicated, in part or
22 whole, or each may have its own secure functions that are inactivated when a system microprocessor becomes the
23 unsecure processor. A switch from secure processing to unsecure processing preferably ensures that any potentially
24 secret information is flushed from CPU registers and any other locations that may become accessible to external
25 analysis in the unsecure state. All secure functions would usually be inaccessible to the system microprocessor in
26 unsecure mode. A person knowledgeable in the art should be able to design such an embodiment that performs to the
27 requirements of the invention. This provides a convenient means of providing an existing UCDPS with a means of
28 integrating two different UCDPSs into one. Of course this scenario might be expanded to any number of system
29 microprocessors within the one package. When multiple system microprocessors are included in the one package,
30 the one that is normally associated with the resident operating system and peripheral arrangement in the UCDPS is
31 referenced in this application as the Host CPU. Any other system microprocessors are referenced as a Grafted CPU.
32 No changes would usually be required to any software to operate the Host CPU, however, other support may be
33 required to simulate the correct environment for a Grafted CPU and one solution may be to include a programmable
34 address trap for the grafted system microprocessor that detects all accesses to resources that need emulation.

35
36 It will be appreciated by those experienced in the art that the embodiment described with reference to Figure 1 may
37 be readily transferred to a location external to the system microprocessor by providing a secure package and
38 replacing the transparent address space of the version within the PCPU with an appropriate address within the
39 UCDPS address space.

40

1 A basic embodiment of an SPD for use external to the system microprocessor is described with reference to Figure 2
2 of the drawings showing a printed circuit board 700 that is capable of connecting with an appropriate socket on the
3 bus expansion of a UCDPS 720 via the gold fingers 701 on the printed circuit board 700. Mounted onto PCB 700
4 are an address decoder 702 to receive address signals from the address bus of the UCDPS 721 and various control
5 lines 722 that it uses to decode the UCDPS side of the dual port memory 704 to a suitable address location in the
6 address map of the UCDPS using chip select line 712. The lower order address lines 723 of the UCDPS together
7 with UCDPS data bus signals 724 and a read/write signal 725 pass from the UCDPS bus via buffer 703 to the
8 UCDPS side of the dual port memory 704 via signal lines 713. The part of 703 that buffers the data lines is
9 bidirectional. A microprocessor 707 includes two interrupt lines 730 and 731 and an external address bus 714 and
10 a valid address signal 733 and a bidirectional data bus 715 and a read/write line 732 and internal programmable
11 non-volatile memory 708 (e.g. flash memory) and a boot routine 735 to load information into non-volatile memory
12 708. A static RAM chip 709 is connected to microprocessor 707 low order address lines of address bus 714 and the
13 data bus 715 and read/write line 732. Static RAM 709 is activated by chip select 740 that is created by the address
14 decoder 705 decoding the high order address lines on address bus 714 in conjunction with valid address signal 733.
15 When static RAM 709 is selected the microprocessor 707 may read and write data to and from 709. The
16 microprocessor 707 side of the dual port memory 704 is attached directly to the 707 data bus 715 and read/write line
17 732 and low order address lines of address bus 714. The microprocessor 707 side of the dual port memory is
18 activated for read and write operations by chip select 750 generated by address decoder 705, from high order address
19 lines on the address bus 714 and the valid address signal 733. A rechargeable battery 710 is included providing
20 backup power via 711 to the microprocessor 707 and the static memory 709. When the the board 700 is plugged into
21 an active UCDPS, the battery 710 is recharged from the system power supply. Microswitch 712 connects to interrupt
22 line 730 causing an interrupt when the tamperproof enclosure 716 is disrupted. The tamperproof housing 716
23 securely encloses 710, 707, 709, 705, 704, 712, and all signal lines that may provide useful information. Interrupt
24 line 731 causes an interrupt to 707 when the address decoder 702 decodes any address within the dual port memory,
25 indicating that the external system microprocessor is accessing the device and that action may be required by
26 microprocessor 707. The microprocessor 707 is normally in low power sleep mode. If awakened by interrupt 730 it
27 immediately sequentially erases the values stored within SRAM 709 using a routine preprogrammed into 707 prior
28 to enclosure in 716. If awakened by 732 it continues processing as required. The SPD as described may be
29 integrated into a single chip. A person experienced in the art would be able to adapt this design to attach the SPD to
30 any suitable non-bus interface. A suitable location may be the parallel port on a shared basis with the printer; the
31 known art for other types of software protection devices describes such a shared interface. The inclusion of a
32 cryptoengine implemented in hardware would enhance decryption processes that are fundamental to the secure and
33 versatile functions provided by an SPD.

34
35 Figure 3 shows a block diagram of the address map for secure functions within the system microprocessor
36 package/die 130 of Figure 1. These secure functions may only be addressed by the secure microprocessor 20 and
37 may not be accessed by external programs other than said external programs providing information that is usually
38 subject to validity checks and decryption before acceptance by the secure microprocessor 20 for further processing.
39 The address decoder 25 decodes a battery backed real time clock/calendar 89 with chip select 140, DMA controller
40 125 with chip select 142, Data Encryption Standard Engine 135 with chip select 143, and if the DES engine is

1 constructed in part or whole from programmable logic devices (preferably SRAM, that may be battery backed if
2 non-volatility is required) that are dynamically programmed as required, these devices are selected by select line
3 141, tamper detect 80 (preferably including a continually powered simple microcontroller to provide continuous
4 security monitoring) selected by 144, A/D converter 75 by select line 145, power management 65 by select 146. The
5 preceding devices would usually have fixed locations in the memory space. They are part of the system functions and
6 the chip selects 140,141,142,143,144,145,146, and any other additional select lines that may be included to access
7 other secure devices, may only be selected if the instruction that outputs an address that is decoded to the preceding
8 chip selects originates from within a memory location in the secure system memory 147, protecting the security of
9 this area from non-system (user) programs - usually user application programs.. One method to do this is to latch the
10 first address of an instruction and compare it with an address block that defines the boundaries of the secure system
11 memory 147. This address block is preferably programmable to allow the size of secure system memory to be varied,
12 however, there will be a known default on reset of the secure microprocessor 20. As an added precaution it is
13 preferable to latch the first address of the preceding instruction and do a similar comparison. This requires any
14 instruction that attempts access to secure functions in this part of the address map to have originated in secure
15 system memory and the instruction prior to it must also have originated in secure system memory. This is to prevent
16 a program that may be executing within a secure user partition from accidentally or deliberately loading the program
17 counter of the secure microprocessor 20 with a value pointing to a secure function with unpredictable results. The
18 address of the first instruction may be determined by including in the microcode of secure microprocessor 20 the
19 generation of a signal to indicate that it is the first address of the instruction (this may already be the case). The
20 program counter contents may also be latched. Chip select 147 from decoder 25 delineates the block of memory
21 allocated to secure system functions. When the secure microprocessor 20 is reset it jumps to an initialisation routine
22 in this memory. The size of this memory is preferably variable to accommodate changing circumstances. This is
23 usually done by programmable boundary registers 160, that are selected by chip select 161. One boundary is usually
24 fixed at the top of the available address space. The programmed value of 160 is supplied to address decode 25 and
25 provided to its address comparators. These methods are well known to the art. Chip select 161 preferably requires
26 the same precautions as regards checking the origin of the instruction as described for 140, 142, etc. Chip select 147
27 decodes the secure system memory. This preferably has the same requirements for two sequential instructions to
28 have originated in secure system memory addresses in order to be decoded. An exception is reset or an interrupt that
29 reset the latches that store the addresses of the two relevant instruction addresses to values that are within the secure
30 system memory. This enables the secure microprocessor 20 to read information from its interrupt handlers. This also
31 provides a method for a user routine to transfer processing back to system memory in a controlled way. A user
32 function may write to an addressable location that generates a user interrupt 180; the system functions may then
33 interact in any predetermined manner to meet the requirements of the user function. The balance of the secure
34 memory is allocated to various user functions. In a multitasking UC DPS, this is preferably partitioned into multiple
35 user partitions. The preferred method is to have one or multiple sets of address boundary registers 170, that may only
36 be programmed by secure system functions decoding select 171, with the value programmed into 170 feeding back
37 to the decode logic 25 to define the current user partition, that is decoded with chip select 148. This permits the
38 available user partitions to be divided on a totally flexible basis as required. When processing transfers from one
39 user partition to another, the secure system functions reprogram the appropriate values. When processing is
40 transferred to a user partition no addresses are decoded outside this partition to prevent a user function

1 compromising the system partition or another user partition. If the program counter is loaded with a value pointing
2 to an address outside the user partition, it will not be decoded and the user function will usually crash. In case of a
3 crash within one of the user partitions a watchdog timer 190 may interrupt 191 the secure microprocessor 20 after a
4 predetermined period. This is preferably a programmable period that may also be used to task switch secure
5 processes in a multitasking environment. Prior to transferring processing to the user partition, the secure
6 microprocessor 20 registers are preferably stacked and cleared of sensitive information and or the registers are
7 duplicated. The dual port memory is decoded by chip select 150. The secure microprocessor 20 may also generate at
8 least one interrupt 195 to the system microprocessor that directs the system microprocessor to an interrupt routine in
9 dual port memory and or any suitable location. This location is preferably read only to the system microprocessor
10 and may be read and written by the secure microprocessor 20. This interrupt may bypass any normal interrupts
11 generated by the UCDPS to the system microprocessor and be processed transparently to the operating system. See
12 known art US Patent 5274834. It may be used for any reason in particular to direct the system microprocessor to
13 perform various functions within the UCDPS transparently to the UCDPS operating system. An interrupt may also
14 be generated by the system microprocessor to the secure microprocessor 20. Interrupts to the secure microprocessor
15 20 are preferably specific to a particular source with sufficient interrupt lines to handle all interrupting devices.

16
17 Within the secure system memory is an area of masked ROM 51 that is usually a fixed amount, usually a fixed
18 amount of flash memory 52 for storing information that survives total loss of power, and usually a variable amount
19 of battery backed static memory 53 that securely stores secret system programs and data. This information may be
20 lost in part or whole, due to accidental reasons, e.g. a flat battery (preferably rechargeable), or by activation of one or
21 multiple tamper detect systems and or failure to comply with the conditions attached to using the SPD and or any
22 other reason. System memory and user memory 54 is described later. Part at least of 53 and or 54 may be replaced
23 by dynamic memory to provide greater memory density. This may particularly apply to secure system functions
24 loaded from external sources as required, and user functions loaded as part of a PSO executing and or any other
25 external information transferred as required.

26
27 Secure System Functions:

28 The system memory of an SPD must be preprogrammed with certain key programs and data prior to shipping to a
29 user (usually as part of a UCDPS). This should be done in a secure environment, using secure methods, and is
30 preferably completed during the manufacturing process. The service provider keeps a record of part at least of the
31 information within each SPD. Once this key information is programmed into the system memory, any other types of
32 programs and or data may be suitably encrypted by the service provider and transferred to a user's SPD (usually
33 while within their UCDPS) using methods that maintain the security of the information. The suitably encrypted
34 information is programmed into the system and or user memory of the SPD on a temporary or permanent basis, and
35 in many cases this will be a transparent, dynamic process that occurs during the execution of various computer
36 programs, particularly PSOs. This method allows almost any type of additional functions to be securely loaded and
37 stored within the system memory, and or allows various programs to be loaded to update and or modify existing
38 system functions and or any other transfer of information for any reason.

39

1 Secure system functions are those functions applicable to the correct operation of the SPD and the provision of
2 required resources to multiple secure user functions. Secure user functions are those applicable to one or multiple
3 PSO loaded into memory of the UCDPS that requires the SPD and system functions within the SPD for its correct
4 operation. Secure user functions are usually an integral part of, or integrally linked with, a particular PSO and
5 loaded into the SPD as required. A PSO that is supplied by the service provider to securely update secure system
6 functions would usually act as a secure user function, although its effect is directed at secure system functions.

7

8 The preferred SPD consists of the following:

9

10 1. It provides a tamperproof environment which is not practical for an unauthorised party to penetrate for any reason
11 including attempts at analysing or tampering with one or multiple secret processes that may be occurring within said
12 tamperproof environment. This tamperproof environment may use a combination of secure packaging, using any
13 known art to monitor the maintenance of the integrity of said secure packaging, together with a method of rapidly
14 invalidating the contents should interference with the package be detected. As the preferred embodiment of the
15 invention stores secret information independently of whether or not the UCDPS is active, part or all of the tamper
16 detect and data invalidating methods preferably remain active on a continual basis. The preferred method is to have
17 the secure microprocessor 20 (Fig 1) and or a microprocessor integrated into tamper detect 80 (Fig 1), continually
18 powered and periodically awakened from a low power sleep mode to perform one or multiple housekeeping
19 functions, including monitoring and or activating various intruder detect processes.

20

21 Secret information that may compromise the secure nature of multiple other SPDs is preferably stored in battery
22 backed Static RAM (SRAM), a storage medium that may be rapidly invalidated by removal of power and or by a
23 specially created subroutine that cycles through the memory changing values and or a specially designed cascade
24 system that triggers automatic invalidations of static memory storage elements as is known to the art (reference
25 Dallas Semiconductors Secure Microcontrollers). The invention allows for any known method and apparatus of
26 detecting physical tampering with the SPD and allows for any method and apparatus of invalidating secret
27 information in any type of memory storage device.

28

29 Secret information that is only likely to compromise the security of a particular SPD may be stored in SRAM,
30 however, information that should survive invalidation of the information within SRAM is preferably stored in non-
31 volatile locations. When this information needs to be programmed and or reprogrammed dynamically in the normal
32 course of operation of the SPD, it is preferable to use flash memory or an equivalent. When the information does not
33 require alteration after initial programming it may use any type of non-volatile memory storage device.

34

35 Information not requiring secrecy (as far as practical) and that is consistent across multiple SPDs is preferably
36 implemented in mask ROM during the manufacture of the SPD. This usually includes initialisation routines to
37 program other information into the SPD. When constructing an SPD that is not within the system CPU, the CPU
38 chosen for the SPD will usually already have a boot or initialisation routine embedded within. Those experienced in
39 the art will appreciate that information stored as masked ROM inside an integrated circuit (IC) package may be
40 analysed, however, this is usually with great difficulty.

1
2 Where certain unique features are required in each SPD at the time of manufacture and secrecy (as far as practical)
3 is not essential, they are preferably implemented by laser programming of masked elements. This usually applies to
4 one or multiple passwords that are applicable to a particular SPD.
5
6 The secret processing device (SPD) is a device that is not practical to tamper with. This device contains various
7 secure functions that may perform useful functions for suitably configured software objects. It also provides various
8 secure functions that permit a provider of protected software objects, referred to as service provider, to create an
9 effective method of renting software to users. A number of alternative methods of securely distributing software are
10 discussed. The method is secure from the perspective of the producer of the software object and provides a
11 convenient means for a potential user to have access to a large amount of software that they only pay for as they use.
12
13 The invention allows that attempts may be made to physically tamper with the SPD. This may be for any reason,
14 including the unauthorised extraction of secure information from the SPD. Secure system tamper detect functions,
15 using any method and apparatus, may be used to detect tampering and or to take direct (that preferably includes
16 immediately erasing and or altering information within part or all secure storage devices) and or indirect (e.g. via
17 error functions) action in the event of tampering. Part of the tamper detect functions allow for any method and
18 apparatus, referenced as secure system continuity functions to confirm that one or multiple of any tamperproof
19 mechanisms remain intact. One method is to include bidirectional logic at each end (or any other location) of the
20 various signal lines to check for continuity of signal traces and or functioning of attached logic elements in those
21 instances where the normal function does not permit this. This bidirectional logic is usually connected, directly and
22 or indirectly, to addressable elements under the control of suitable software routines. The invention also allows for
23 any method and apparatus to detect loss of clock to the realtime clock/calendar and or any one or multiple other
24 clocked elements, including routines that periodically read these clocked devices (directly and or indirectly) to
25 ensure that there are the expected incremental changes secondary to an active clock. It is preferable that part or all of
26 the tamper detect mechanisms remain functional when the system power supply is removed. This may include using
27 battery power to maintain one or multiple microprocessors within the device in an operational mode, enabling them
28 to execute various system functions. Loss of battery voltage below a predetermined threshold (as detected by an
29 integrated A/D converter) may trigger the erasure of part or all secure elements. It is preferable that an independently
30 timed function is implemented (e.g. RC network) that must be periodically refreshed by one or multiple
31 microprocessors. This confirms the presence of an active CPU and failure to periodically refresh this function would
32 usually cause a default erasure and or alteration of secure storage elements.
33
34 The invention allows that various errors and or validity failures and or any processing error and or any other event
35 may be recorded by secure system error monitoring routines (usually implemented within secure system memory).
36 These may perform any functions, that may include:
37 recording abnormal events; and or
38 in response to a predetermined number and or types of abnormal events (and or any other reason) take one or
39 multiple actions (that may be any action, including calling other functions to partially or totally disable the device);
40 and or

1 return processing to the system CPU (with or without error reporting).
2
3 There may be a requirement to disable part or all of the SPD and or part or all of other apparatus that the SPD may
4 be integrated within (e.g. system CPU). The functions to perform this are referenced as secure system disable
5 functions and they may be implemented using any method and apparatus, including:
6 the generation of various clocks (and or any other meaningful signals) that trigger immediate erasure of volatile
7 elements; and or
8 setting/clearing of flags (preferably in non-volatile locations) that may be read by various other functions that will
9 not continue (and or any other outcome) in the event of an unacceptable value within a flag.
10
11 The invention also allows for any method and apparatus that may temporarily prevent, in part or whole, action by the
12 disable functions. This may be for any reason, however, the primary one is to stop inadvertent triggering of these
13 functions during software development. The invention allows for any method and apparatus that prevents
14 infringement of system security when the disable functions are in part or whole temporarily inactive.
15
16 2. It provides one or multiple blocks of memory arranged in a manner that prevents unauthorised analysis of the
17 contents of such memory unless intended. This memory is referred to as secure memory. This may apply even if part
18 or all of the memory contains information that is not secret.
19
20 The memory blocks may use any types of memory storage device, in any mix and combination. There are preferred
21 types of memory storage devices to meet the requirements of specific functions.
22
23 The primary purpose of secure memory is to provide part of an apparatus that, when combined with a secure method
24 of processing information within the secure memory and a means of transferring information between the SPD and
25 external locations, allows certain secret processes to occur and or certain secret information to be securely stored.
26 The processing of information within secure memory may include the use of any mix of secure and unsecure
27 programs and or data, and any interaction with resources that are external to the SPD.
28
29 An SPD usually has one or multiple blocks of memory storage devices that may consist of any type and combination
30 of memory storage devices arranged to make it not practical for unauthorised parties to analyse the values stored
31 within part or all of said memory storage devices.
32
33 The memory storage devices preferably:
34
35 (a) include one or multiple blocks of Static RAM that are made non-volatile by connection to a non-disruptable
36 power source that is preferably a rechargeable battery integrated into the device and or its enclosure, and or a
37 rechargeable battery external to said device, and said Static RAM is used in part or whole to store secret information
38 that should usually be invalidated in the event of any tampering with said device, and said Static RAM is preferably
39 connected directly and or indirectly with one or multiple methods and apparatus to detect said tampering and
40 invalidate and or activate invalidation, of part or all of said secret information as a result of said tampering. The

1 invention also allows for the inclusion of any method and apparatus to invalidate in part or all secret information
2 stored within said static RAM for any other reason. This memory usually stores:
3 (i) secret system functions implemented at least in part as software routines, that need to be maintained in secrecy
4 (as far as practical) and that cannot be stored in encrypted format in an external location and loaded and decrypted as
5 required. An example of this may be the master decryption algorithm and or keys. If this was loaded from an
6 external location it may be analysed and used to break the security of other encrypted information. Partial loading of
7 decryption algorithms may be possible as long as sufficient function is kept securely within the SPD. Said sufficient
8 function may in part or whole be a hardware implementation of a decryption algorithm.
9 (ii) information that may or may not need to be secret that is required to correctly interface with externally available
10 information, this may include the loading of other information.
11 (iii) information that it is determined, for any reason should be within the SPD on a continual basis.
12 (iv) information that is loaded from external resources. This may include additional secure system functions loaded
13 in encrypted format and subsequently decrypted and may include appropriately encrypted objects supplied by an
14 authorised party to modify information within the SPD.
15
16 The information described in (i), (ii), (iii) and (iv) constitutes part of the secure system functions (53 of figure 3) and
17 consists of information that is known to be available within, or able to be loaded within, the device when required to
18 perform the functions that are an integral part of the SPD. System functions are also known to have been carefully
19 prepared and scrutinised in a secure environment to ensure that they do not corrupt and or compromise the secrecy of
20 information within the SPD. Those secure system functions that are loaded into the SPD in encrypted format usually
21 have tamperproof validity checking processes integrated into their structure to ensure the validity of the information
22 prior to associating it with other secure system functions. That part of the secure memory that includes secure system
23 functions is referenced as secure system memory.
24
25 (v) other information that may be loaded into the battery backed SRAM and may include one or multiple secure user
26 functions (54 of figure 3). These are usually software objects supplied by various producers that have a requirement
27 for interaction with the SPD. They usually require appropriate conversion of the software object by an authorised
28 service provider to one that may be recognised and processed by the SPD and such an object is usually referenced as
29 protected software object or PSO. A PSO is usually encrypted and preferably has appropriate validity checking
30 mechanisms included to ensure that the information is as supplied by the service provider. Those parts of the PSO
31 that are to be transferred to locations within the SPD, whether data and or computer instructions, are referenced as
32 secure user functions. In applications where this information is data that is to be processed securely using secure
33 system functions, accidental and or deliberate tampering with the data usually has no potential unwelcome
34 consequences within the SPD as the processing is performed by known processes.
35
36 (b) static RAM (SRAM) that is not battery backed and or dynamic memory may be used for secure system functions
37 described in the preceding (a) part (iv), and or secure user functions in (a) part (v), and or any other information
38 loaded into the SPD.
39

1 (c) an area of programmable and or reprogrammable memory that remains non-volatile when all power is lost. This
2 preferably includes one or multiple blocks of intrinsically non-volatile and reprogrammable memory e.g. flash
3 memory and or EEROM, including any required componentry to support programming, erasure and reprogramming
4 of said flash memory and or EEROM. Particular applications of this area are the storage of information that should
5 survive an erasure of SRAM for any reason, including accidental erasure. One of the features of the SPD is its
6 capability, with appropriate software, to select random encryption keys and validity check sums, and use these to
7 encrypt information stored externally, preferably on a mass storage device. This information may need to remain
8 retrievable if the SRAM contents are corrupted. By retaining the keys to this information in non-volatile locations, a
9 suitably protected routine may be used to retrieve this information by the service provider. It also prevents tampering
10 with externally encrypted information as the decryption key is inaccessible and may be varied every time.

11
12 (d) includes one or multiple blocks of memory of mask ROM that is programmed at the time of fabricating the
13 memory storage devices and said mask ROM preferably includes an area that may be customised to create unique
14 information for each device, one method of customising the device is with a laser. This is usually used to initially
15 program data into other storage devices.

16
17 The current system functions within an SPD preferably have a version number stored in an externally accessible
18 location, eg. dual port memory 19 of figure 1 that may be read by PSOs to ensure the SPD has the necessary
19 resources to meet the requirements of the PSO.

20
21 3. It provides at least one secure microprocessor 20 and a method of decoding part or all of the secure memory and
22 any other addressable functions (e.g. timer, realtime clock, decryption/encryption engines, interfaces, etc) into the
23 address space of the secure microprocessor 20. The microprocessor is designed such that secret information that it
24 reads and or writes and or processes, in part or whole, is not exposed to unauthorised analysis.

25
26 The secure microprocessor 20 may be continually powered to perform reliable tamper detection and invalidation.
27 The power source is usually shared with the battery backed SRAM and where present, the realtime clock/calendar.

28
29 It is preferable that the reset line on the secure microprocessor is connected to the reset line of the host UCDPS,
30 enabling it to perform error checking on internal stored information prior to performing functions required by the
31 UCDPS.

32
33 The secure microprocessor on reset (and or any other appropriate event) and or as part of its normal functions may
34 perform various housekeeping duties while waiting for one or multiple interrupts generated by the UCDPS, and or
35 the reading of one or multiple appropriate values from one or more polled addresses, that may also be directly and or
36 indirectly written to by the system microprocessor, and or any other method that activates the microprocessor and or
37 any one or multiple other functions of the SPD to further interact with the UCDPS as required.

38
39 4. The SPD predominantly is a secret processor of information and a secure and secret repository of information, that
40 in part or whole is generated (including by decryption) within the SPD. It is an essential function that there is a

1 means of transferring information in and out of the SPD without compromising the security of information that must
2 remain secret. This entails two basic requirements:
3
4 (a) The provision of one or multiple physical interfaces between SPD and sources of information. The invention
5 allows for any known interface. This includes information that is transferred via the bus of the UCDPS, that is the
6 usual method when the software objects using the SPD are executing and or being processed by the system
7 microprocessor, and or information entering through one or multiple ports that may be read by the secure
8 microprocessor and or any other function within the SPD.
9
10 The preferred interfaces include any ports that are part of the secure microprocessor or any other part of the SPD,
11 dual port memory 19, latches and or registers (unidirectional and or bidirectional), FIFO memory, a facility for the
12 secure microprocessor to have direct access to the address bus of the UCDPS and move information under
13 programmed control and or by direct memory access (DMA).
14
15 (b) a method for the SPD and UCDPS to determine which locations have valid information and a method of acting
16 on this information. The information may be commands and or programs requiring execution and or data for any
17 reason and or any other information. This is a function of the secure system functions and specifically those
18 referenced as secure system I/O functions. They require similar processes to those provided by any operating system
19 and are within the expertise of those experienced in the art of writing operating systems. Moreover, as the SPD
20 includes functions to load and execute externally supplied software objects that may securely modify the various
21 secure system functions, more flexibility is provided with an SPD than many UCDPSs having part of their operating
22 system in memory that is not easily modified.
23
24 The preferred embodiments of the invention provide a dual port memory 19 that is accessible by the secure
25 microprocessor and the system microprocessor. This occupies a predetermined part of the address map (that may be
26 programmable) as previously described with reference to Figures 1 and 3.
27
28 The next part of the description may be better understood by reference to Figure 4 of the drawings that shows:
29
30 A system port structure 199 is established that may have one or multiple addresses which the system microprocessor
31 writes to, referenced as system command input port 200 and one or multiple addresses that it reads from, referenced
32 as system command output port 201. The SPD reads command input ports and writes to command output ports. As
33 these are usually part of a block of memory, they may be dynamically reconfigured by appropriate interaction
34 between system microprocessor 1 and secure microprocessor 20. This reconfiguring may change locations and or the
35 number of addresses constituting a port. It is preferable to have a system input data port 202 for the transfer of
36 information other than commands from UCDPS to SPD and a system output port 203 for non-command transfers
37 from SPD to UCDPS. In the case of dual port memory a large block of addresses may be allocated for non-command
38 information and the addresses and sizes may be dynamically configured. The actual allocation of input and output
39 ports is preferably a function of the SPD and is likely to be a dynamic state. In a single tasking environment this may
40 be the only interfacing required. The inclusion of a DMA channel 125 on the SPD is the preferred method of moving

1 large blocks of information in and out of the secure memory 53, 54 of the SPD. Address and control lines 220 and
2 data lines 221 from the DMA controller 125 are multiplexed with similar signals from system microprocessor 230
3 are multiplexed in 235 for interface with external memory. Address and control lines 222 and data lines 223 are
4 multiplexed (not shown) with similar signals from secure microprocessor 20 for transferring information to and from
5 secure memory 53 and 54.

6

7 The invention also allows for the SPD to handle the requirements of multiple PSOs in a multitasking environment
8 and that the system command and data ports as described may be sufficient if the UCDPS operating system is
9 modified to send a command to an appropriate location in a command port to instruct the SPD of a task change and
10 does not proceed until the command is acknowledged.

11

12 The preferred method is to use the system command and data ports for establishing certain parameters within the
13 SPD when a PSO first requires access to the SPD. The PSO would usually send information requesting a user
14 partition 54 of Figure 3 and a user port structure 205 of Figure 4. The SPD would usually respond with availability
15 of this memory and dynamically configure a user command input port 206 and or user command output port 207
16 and or user input data port 208 and or user data output port 209. The PSO stores these port addresses in a suitable
17 location in its own address space and directs all commands and other information to and from these user ports until
18 otherwise appropriate. A multitasking kernel within secure system functions is preferably responsible for such port
19 configuration as part of its functions. Additional PSOs create their own user ports, e.g. 210 and 215 of Figure 4. The
20 space used by these ports is reallocated when a software object terminates interaction with the SPD. Any one or
21 multiple user ports may be dynamically reconfigured as required while still in use with a particular PSO. This
22 process permits the SPD to be transparent to the UCDPS task handler.

23

24 5. Secure System and Secure User Partitions:

25 If the SPD is to provide any useful processing of information supplied, it requires a method of transferring
26 information into secure areas where it may be further processed. As described, a potential unsecure process is
27 introduced into an SPD once the facility is provided to load externally supplied information into secure memory that
28 in part or whole consists of executable code. PSOs that are to modify the secure system functions are usually
29 provided by the service provider from software objects in their control and the security is good. When a PSO is
30 produced by a Producer, there can be no such guarantee of the integrity of the contained program code. The
31 execution of this material may read information from secure system functions and write it to external locations. In a
32 multiuser system, it may also compromise information relevant to another PSO.

33

34 The preferred method is to partition the available secure memory into partitions as previously described that
35 includes a system partition and one or multiple user partitions. Programs within a system partition may access any
36 secure memory address. Programs within a user partition are confined to their own partition. This is implemented
37 using dual latching of instruction sources as previously described. This protects system integrity and the integrity of
38 one user partition from any other. An alternative is to perform this function with software, by checking that each
39 instruction executing within a particular user partition is not intended to make an unauthorised access to system

1 memory and or other user memory. Another solution would be to allocate a separate microprocessor to one or
2 multiple user functions.

3

4 When the secure system kernel switches processing between user functions, it programs logic with the address
5 boundaries of the current user partition that is compared with an instruction. A separate user partition is allocated to
6 each user function.

7

8 The invention allows for any method and apparatus that prevents any particular user function from accessing, in an
9 unauthorised manner, secure information within system partitions and or other secure user partitions. The method
10 does allow valid transfers of processing across system and user functions.

11 It is preferable that the size of the partitions may be varied, preferably under the control of secure system functions.

12

13 6. Initial Programming, Reprogramming and Erasure of secret information:

14 The invention allows for secure system initialisation functions (SSIF) that may use any method and apparatus to
15 initially program secure system functions into secure locations within the SPD, preferably into battery backed static
16 RAM. This usually occurs prior to release of the SPD from a secure environment. The SSIF are part of the secure
17 system functions, however, they include information that it preferably not made public, however, the invention is not
18 compromised should this occur. For this reason they are suitable for use in mask ROM. Any other secure system
19 functions may be included into mask ROM, however, this is not the preferred location for any information of a
20 sensitive nature. In addition to security factors, the inclusion of the majority of secure system functions in
21 reprogrammable storage elements allows them to be readily updated. The invention allows that that the SSIF may
22 be used later to erase and or modify and or reprogram the SPD at a later date. The invention also allows that part or
23 all of the functions within the SSIF may be called by other secure functions as part of the normal operation of the
24 SPD. For example the routines to load information from external locations and to program information into flash
25 memory have obvious multiple uses. Certain provisions within the SSIF should only be capable of use when it is
26 known that secure information within the device is invalid.

27

28 The preferred method and apparatus is to store the Secure System Initialisation Functions within (preferably
29 secure) storage locations prior to encapsulation (that may be the package of an IC and or any other additional
30 packaging) of the device at the time of manufacture. As a minimum, the SSIF information included within the
31 device at the time of manufacture should be sufficient to load and or program other information into the device and
32 where necessary initiate processing of said other information. This provides an SPD that may then modify itself as
33 required. Said other information may be any information and may include additions to the SSIF not included at
34 manufacture. The storage locations should retain SSIF functions (in part or whole) when other information within
35 the device is erased for any reason. The SSIF may include any required support hardware to program particular
36 storage devices, eg. charge pumps and or supply of special voltages and or timers and or glass windows to erase
37 EPROM. The SSIF is usually implemented within secure memory (that is preferably mask ROM, however, it may
38 be any suitable type of storage device) and usually includes functions:

39

40 to respond to a command to activate one or multiple SSIF functions (and or any other necessary commands); and or

1 to retrieve externally supplied information, that may use any method and apparatus provided for in a particular SPD
2 and to program part or all of this information and or any other information into required locations; and or
3 to finish programming; and or
4 to verify that the programmed information is error free; and or
5 to terminate the process such that various applicable functions remain available as secure system resources; and or
6 to direct processing to part of the information that has been programmed (and or otherwise initiate access to this
7 information).

8

9 (The ability to load information and subsequently direct processing to this information is a key aspect of the
10 invention. With the addition of a suitable decryption method within the SPD, the SPD may load encrypted
11 information, decrypt this information and then direct processing to said decrypted information. The addition of
12 routines to pass information back to external locations completes the process. These functions are described in detail
13 later).

14

15 The SSIF and any subsequent secure system functions may load information from any relevant external location to
16 assist the process and or may call routines within external locations to assist the process.

17

18 Any SSIF function that allows programmed information to be read back for verification (and it is preferable that this
19 occurs) may use any method and apparatus to prevent a user from activating this function at a later date and possibly
20 being able to access secret information. The preferred method flags a non-volatile programable location once the
21 readback process is complete in a manner that does not leave said flag clear in the event of a partial readback. The
22 preferred method to prevent the flag remaining clear in the event of a partial readback is to activate a watchdog timer
23 that times out after a predetermined interval and sets the flag preventing further verification readback by triggering
24 a flip flop. It is preferable said flag can only be cleared after secure storage elements have been erased and or
25 otherwise suitably modified. This is not a function that should be available in unsecure environments.

26

27 Disclosure of the information constituting the actual SSIF is unlikely to jeopardise the security of other secret
28 information, however, it is preferable that unauthorised parties are prevented from initialising and or erasing and or
29 reprogramming the device and any method and apparatus may be used to implement this. It is preferable that these
30 processes are password protected (using any password system) against unauthorised use.

31

32 One method of implementing SSIF would be to serially clock the required information into the device via latches
33 (that may require a certain predetermined sequence to activate the process). This may not require any predetermined
34 software routines within the device.

35

36 The preferred method uses a secure software routine executing from within secure ROM that uses the Timed
37 Password Access process described below to activate programs that perform the functions previously described for a
38 SSIF, transferring the relevant externally supplied (and usually secret) information to the relevant internal storage
39 devices and subsequently initiating processing of this information.

40

1 The actual method of programming information into the storage devices will depend on the type of storage device
2 and may use any known method.
3
4 The timed password access method makes it unlikely that the password protection will be defeated, while retaining
5 functionality for those parties with the necessary knowledge, even in the presence of previous unsuccessful attempts
6 at programming and or deliberate attempts to inactivate the device (eg. computer viruses). This contrasts with
7 password systems that permanently inactivate the process after a predetermined number of attempts, possibly
8 preventing further programming of the device by authorised parties.
9
10 The invention allows that a preferably unique password is programmed (usually as part of SSIF) into each device.
11 Without access to this unique password the probability of unauthorised activation of SSIF is not a practical outcome.
12
13 In an SPD integrated within a system microprocessor, particularly one with multiple microprocessors within, the
14 SSIF may reside in memory locations exclusive to one of the on chip CPUs and be transferred where necessary,
15 using any internal mechanisms (including software), to any required storage devices; and or
16 may be loaded into memory locations shared by multiple CPU's within the package;
17
18 and or may be loaded into multiple locations, each location of which is exclusive to a particular CPU within the
19 device.
20
21 The invention allows that only one CPU or a subset of available CPU's may load information for other CPU's, and
22 or that particular CPU's load information for their own use.
23
24 The preferred method of activating the SSIF functions when the SPD is within the system microprocessor is to load
25 the password into one or multiple CPU registers and execute a specially created instruction that that activates SSIF
26 to read the password and continue as appropriate. An alternative is to include the functions that detect and process
27 the post instruction symbol stream as described later.
28
29 The timed password access (also referenced as TPA) may use any method and apparatus. It prevents any practical
30 gain from attempting unauthorised access to any particular password protected event. It is based on a password of
31 such complexity that in practice it would take such a long time to try all the permutations that it is not practical to
32 gain access to the protected event. Said complexity is assisted by incorporating a delay mechanism that restricts the
33 frequency of attempted access. Said delay may be variable for any reason (e.g. to allow for legitimate errors) and
34 may be created using any method including software loops and or physical delays. The delay may be a hierarchical
35 system that includes different delays depending on the number of incorrect attempts at access. It is preferable that
36 said delay is unaffected by powering down of the device to prevent rapid power cycling defeating delay mechanisms.
37 One method and apparatus consists of the following steps:
38 a) create one or more password keys that are stored securely.
39 b) create a means to store a cumulative count in a device that is reprogrammable and preferably non-volatile.

- 1 c) create a means to generate a known time interval. The invention allows for embodiments allowing a variable
- 2 interval, this is most readily achieved by a software loop.
- 3 d) create a means to input a password, eg create a specific instruction that can pass externally supplied information
- 4 to the relevant routines.
- 5 e) create a means to input function required should password succeed (not required if only one option).
- 6 f) user activates d) and e) including transferring password and target function to the process.
- 7 g) check the value in cumulative count in b).
- 8 h) if less than certain predetermined value then go to step j) else proceed.
- 9 i) invoke c) to generate time delay.
- 10 j) increment the value in b).
- 11 k) confirm step j) has occurred if there is a chance that external influences may interfere with j).
- 12 l) input password using d) and compare with key in a). If a match go to step o), else proceed.
- 13 m) set flag in external memory to indicate failed attempt at calling program.
- 14 n) exit, to try again enter at f). (if predetermined count above c) retry will be immediate, otherwise a delay will be
- 15 encountered every time).
- 16 o) clear flag in external memory to indicate success.
- 17 p) proceed with called process.
- 18 q) return to external memory when finished.
- 19 Note: for passwords that protect access to processes that are implemented after destruction or alteration of erasable
- 20 areas, software routines and associated key codes should be stored within memory that is not erased.
- 21 The advantage of TPA over a limited number of attempts that then blocks the system, is that it prevents the
- 22 accidental and or deliberate permanent disablement of part or all of the device. The invention allows for a mix of
- 23 methods.
- 24
- 25 Electronic Signature: One or more processes during manufacture and or initial programming and or normal
- 26 operation of the invention may need to identify parameters unique to a particular PCPU and or ESPD and or unique
- 27 to a particular group of PCPUs and or ESPDs (for any reason, including for example, referencing a secure database
- 28 to determine a password to activate the initialisation program described above). This may be done by any method
- 29 known to the art including physical markings on the outside of the CPU package, however, the invention allows for
- 30 one or multiple serial numbers and or any other identifying symbols to be included within the device, usually at the
- 31 time of manufacture. These are amenable to retrieval under program control and or any other form of automatic
- 32 process using any method and apparatus. This provides an automatic method of uniquely identifying a particular
- 33 device and or group of devices. This is referenced as an electronic signature and is usually included as part of the
- 34 SSIF. Said one or multiple electronic signatures may be transferred to an external location using any method and
- 35 apparatus and used by an authorised party as an index to secure information stored within that particular device (and
- 36 or for any other reason). The preferred method when the device is a PCPU is to create a specific instruction that
- 37 when executed stores said serial number from a non-volatile storage location within SSIF to a predetermined CPU
- 38 register. This process is usually accessible to anyone, although it may be protected by passwords and or any other
- 39 method. For ESPDs the serial number is usually read from an addressable location within the ESPD by the system
- 40 CPU. In the case of the ESPD described with reference to figure one, the secure system interface functions

1 programmed into flash memory 708 would include the electronic signature and when the microprocessor 707 is first
2 activated by an interrupt on 731 after programming of said secure system initialisation functions, a routine would
3 transfer the electronic signature to a predetermined location in the dual port memory 704, where it is accessible to
4 the system microprocessor.

5

6 The invention allows that a secure system user password function may be included within one or multiple PCPUs
7 and or one or multiple ESPDs and this may be required to activate part and or all of the invention. In the case of a
8 system CPU it may also be required to enable the normal processing functions of the device, providing a secure
9 method of stopping unauthorised use of the UC DPS containing said system CPU. Any method and apparatus may
10 be used to implement this function. The usual presence of programable memory and programable non-volatile
11 storage elements provide for a plurality of methods. The invention allows for a multi-tiered password system. The
12 preferred embodiment is a time based password system (as discussed elsewhere) that resides in secure system
13 memory and activates routines that reverse various locks placed on part or all of the device.

14

15 The password functions usually include routines to disable part or all of the device in response to a specific
16 command, a method that requires the user to specifically disable the SPD, and preferably requires entry of the correct
17 password; and or functions (usually implemented in hardware) that disable part or all of the device in response to
18 reset and or power down and or any other criteria including automatic timeout (preferably programable), the
19 password processing system is not usually disabled; these functions automatically disable the SPD and or other
20 applicable devices and require the correct password to reactivate the SPD and or other applicable devices.

21

22 The password(s) is usually stored in secure non-volatile system memory. The device may be shipped to the user with
23 a known default password and or the password system disabled. Entry to the password system may use any method.
24 In the case of a PCPU this may include use of a special instruction and or a suitable Post Instruction Symbol Stream
25 (PISS). In the case of a ESPD it may involve passing commands using one or multiple methods as described
26 elsewhere in this application, usually by writing and or reading predetermined address locations. A user accessing
27 the device with the correct password may be able to change passwords.

28

29 The password system is usually constructed to allow the service provider to reinitiate or disable said password
30 system by supplying an appropriate software object, preferably a PSO.

31

32 The inclusion of at least one unique and secure code within each device together with other suitable support
33 resources allows a plurality of methods of secure information transfers to be established between an information
34 provider with access to the secure contents of the device, and or provides for the secure transfer of information in the
35 reverse direction, and or permits information to be specifically encrypted for a particular secure system. These are
36 referenced as system local code functions and they assist the implementation of multiple secure applications,
37 including the secure transfer of information to a device that can verify the source and or validity of the information,
38 and or the secure supply of information from a particular device that the can be verified for validity and source by an
39 information receiver (with access to the secure information within the originating secure system CPU); this may be
40 used for any reason including secure communications and or the secure transfer of electronic funds.

1
2 The inclusion of one or multiple system group code functions that are identical across a particular group of devices
3 (e.g. those destined for the same country) may be used for any reason. This may include the restriction of certain
4 PSOs to particular group codes. One or multiple group codes may be common to all SPDs. The invention allows that
5 part or all of group codes may be user programmable and or password protected. This may allow, for example,
6 parents to restrict childrens access to particular PSOs.
7
8 The secure local and or group codes may be data and or actual computer instructions.
9
10 The effectiveness of the software distribution system forming part of this application is partly dependent on a service
11 provider having access to secure information within each SPD and that some of this information is common to
12 multiple SPDs enabling creation of PSOs that have general application, and that some information is specific to a
13 particular SPD.
14
15 The inclusion of secure system command functions to detect instructions (that may be implied instructions) amongst
16 information supplied to the SPD (using any method and apparatus) and or generated by a secure user function and or
17 generated by secure system functions requesting the SPD to perform certain tasks. These tasks may be any and may
18 include:
19 commence execution of internal programs from any source; and or
20 pass data received from external sources to internal functions; and or
21 receive a request from internal functions to transfer processing back to the system CPU for any reason; and or
22 accept data from internal functions for transfer to a location readable by the system CPU; and or
23 provide a command structure within the SPD to co-ordinate other system functions and, where appropriate, interact
24 with secure user functions; and or
25 where applicable, co-ordinate interaction with realtime decryption processes; and or
26 any other required function.
27
28 The invention allows for any method that permits an SPD to monitor a PSO as it is executed in order to detect
29 various specially constructed process transfer instructions and or other suitable markers that indicate that interaction
30 with the SPD is required. This particularly applies to a PCPU, where the method usually involves the transfer of
31 processing from external unsecure memory to internal secure locations for continued processing by the system
32 microprocessor using secure methods and or by other embedded microprocessors (that may include other system
33 microprocessors, and or the activation of realtime decryption use encrypted information in external location.
34
35 The process transfer instruction may inherently direct external programs to the appropriate internal function or may
36 require a post instruction symbol stream as described with reference to the preferred embodiment.
37
38 Secure system command functions also include any functions to transfer processing back to the appropriate PSO.
39

- 1 The secure system command function should be structured so that entry to secure system functions is in a regulated
2 manner. This is readily achieved for an ESPD where interfacing may be directed to a limited number of addressable
3 locations that may have various validity checking performed on the data. The process is more complex for a PCPU
4 and described in more detail with reference to a PCPU.
5
- 6 An important function of secure system command functions is to direct the decryption of incoming encrypted
7 information, direct the transfer of the decrypted information to a suitable location and where this decrypted
8 information consists of computer instructions, direct execution to the relevant starting point in the decrypted program
9 and provide any necessary support functions as said computer program is executed. When the incoming encrypted
10 information is data this should be processed as required, which may include appropriately linking it with any
11 internal and or external programs and or data and or special purpose functions (e.g. the data may be used to
12 configure programmable logic, creating its own decryption engine) including a linked computer program also
13 transferred in encrypted format. The command functions also direct the return of execution and or data to external
14 locations as required.
15
- 16 7. The invention also allows that one or multiple hardware devices within the SPD may actually be fabricated in part
17 or whole from programmable logic devices. This particularly applies to encryption/decryption engines that may be
18 dynamically engineered as required. The preferred type of programmable logic is that known to the art (refer to
19 programmable gate arrays by Xylinix) using battery backed static memory to create the interconnections between
20 various logic gates, as this may be rapidly erased if required. The information to transfer this information to the
21 programmable logic elements is preferably via one or multiple addressable locations, and is preferably parallel data.
22 Part or all of such devices may need programming prior to leaving a secure location.
23
- 24 8. Secure Decryption, Secure Processing, Secure Decryption and Processing, Secure Processing of Information
25 Unique to the SPD. The system functions should provide suitable software routines such that, when requested by
26 appropriate commands, they perform a combination of functions that affect any combination of the following:
- 27 • for the secure transfer of at least a portion of encrypted information constituting part or all of a software object
28 from a location external to said physical device, to a location internal to said physical device, wherein said
29 physical device securely decrypts part or all of said encrypted information within said physical device in
30 conjunction and or subsequent to said transfer and
 - 31 • may initiate and securely process part or all of the ensuing decrypted information in conjunction and or
32 subsequent to the decryption process and
 - 33 • may interact in any way with any other internal and or external information to correctly said process and may
34 terminate said process as required and
 - 35 • said terminate may transfer data and or execution to any other internal and or external location, including the
36 external software object and
 - 37 • the preceding processes occur in a manner that minimises or eliminates analysis of part or all of the decrypted
38 instructions and or data; and or

- 1 • that includes computer instructions and or data securely programmed within said physical device and a facility
2 for an external software object to transfer processing to said computer instructions and or data securely
3 programmed within said physical device, and the capability of processing part or all said securely programmed
4 within in a secure manner, interacting in any way with any other internal and or external information to
5 correctly said process and
- 6 • may terminate said process as required and
- 7 • said terminate may transfer data and or execution to any other internal and or external location, including the
8 external software object and
- 9 • the preceding processes occur in a manner that minimises or eliminates analysis of secret information; and or
- 10 • with the capability of being suitably requested by an external software object to provide information securely
11 stored within.

12

13 The secure system decryption/encryption functions (together with the necessary command functions to load
14 encrypted information and or to execute, and or otherwise manipulate, the information decoded from this encrypted
15 information, possibly in conjunction with clear code and or other decoded information) may eliminate the
16 requirement to preload specific secure user functions into the device prior to supplying said device to a user. Instead
17 each PSO may include the secure user function as encrypted information included within the PSO supplied to a user,
18 resulting in a device that can securely process part or all of a diversity of software objects. As suitable system
19 command functions may be constructed to dynamically load blocks of encrypted information in and out of secure
20 user (and or system) memory, much larger portions of encrypted information may be utilised as part of a software
21 object than is the case with devices dependent on secure information preprogrammed into a limited amount of secure
22 user (and or system) memory.

23

24 In addition to decrypting and executing the equivalent of secure executable user functions, the invention also allows
25 that the device may securely add to and or edit secure system functions using a similar process.

26

27 The invention also allows for part of the secure system functions to be loaded (usually in encrypted format) into the
28 device from external storage each time a UCDPS is booted (and or on any other basis).

29

30 The security of the secure system routines and in particular secure system decryption routines stored within the SPD
31 is pivotal to maintaining the security of processes using the device. The information within secure system functions
32 must be protected to a level that makes it not practical to defeat and while any storage device may be used to retain
33 the secure system functions within the device, the preferred method uses battery backed static memory. This can be
34 rapidly erased in the event of tampering, and such a requirement particularly applies to any system functions that are
35 stored in decoded format.

36

37 The transfer of information from one location to another may result in transmission errors and the invention allows
38 for secure system error detection functions that may use any known method and apparatus to detect and or correct
39 these errors.

1

2 As the usual location of the SPD is within the UC DPS, information that is to be transferred to the SPD may be
3 accessible and deliberately modified, e.g. computer viruses and or attempts to reverse engineer the SPD. The
4 invention allows for secure system validity checking functions, that may use any method and apparatus to verify that
5 the information supplied to the SPD is as intended by the information provider, and or take any required actions that
6 may include directly or indirectly (usually via secure system error monitoring routines) disabling part or all of the
7 SPD. Where applicable, this may include the erasure and or alteration of secure information.

8

9 The use of cyclic redundancy checking (or CRC) of information generated by a service provider and embedded
10 within a PSO and then encrypted is one method of providing secure validity checking functions. The reversal of this
11 process in the SPD may use any combination of hardware and software methods. The process is well known to the
12 art.

13

14 9. Secure system decryption/encryption functions: The decryption functions may in part or whole be implemented in
15 software to decrypt externally supplied and encrypted information using any known methods, including the data
16 encryption standard. One or multiple hardware based encryption/decryption engines may perform the decryption, in
17 part or whole. Such an engine is one compatible with the Data Encryption Standard (DES). The method of using
18 predetermined processes located within the SPD to decrypt (and encrypt) information is referenced as the Standard
19 Decryption Process in this application. Standard Decryption Processes may require the supply of various codes to
20 function correctly. The original cryptography processes were developed for the secure communication of information
21 between parties and they work well when this is the primary motive. When the purpose of encryption is to enable
22 one party, in this case the producer, to encrypt information to protect it against unauthorised use, and the second
23 party is a user who may prefer that the information was not encrypted, then the original basis for secure
24 cryptography changes, and the premise for security is based on the fact that said second party will receive
25 information, however it will be difficult for them to access it in clear code. This has resulted in various specialised
26 devices to decrypt information. As described this method does not provide a system that is 'not practical' to defeat.
27 The Oscar method of secretly decrypting and executing information provides a method that is not practical to defeat.

28

29 The capability of supplying an SPD with a PSO that can be made to perform any desired function within an SPD
30 that is consistent with available resources and constraints of said SPD, allows said SPD to be dynamically modified
31 to perform any function as required. This permits a PSO and or any other internal and or external function to actually
32 request one or multiple decryption functions to be loaded into the SPD. Said decryption functions may include
33 information that is used to dynamically manufacture a hardware decryption engine from programmable logic within
34 said SPD.

35

36 The capability of significantly varying the decryption process, and or constructing hardware cipher engines from
37 volatile electrical connections that cease to exist when subjected to analysis, and or dynamically engineering cipher
38 engines to suit a PSO makes characterisation of the decryption process very difficult. The known art does not
39 describe such a method and apparatus, which this invention references as Dynamic Decryption in this application.

40

1 By including one or multiple decryption processes within an actual PSO, the decryption process can become self
2 modifying with the instructions of the actual PSO varying decryption parameters and or decryption algorithms and
3 or installing, in part or whole, one or multiple new decryption algorithms during the process of executing the PSO
4 that are further used to decrypt additional parts of the PSO. This may occur on multiple occasions, in any
5 combination, during execution of the program. The key to this process is to include with the PSO a sub-routine that
6 can be recognised and executed by functions within the SPD, and said sub-routine initiates the process of unlocking
7 the subsequent encrypted material. Said sub-routine is encrypted using a process that is known to be reversible by
8 functions within the SPD. The known art does not describe such a method and apparatus, which this invention
9 references as Recursive Decryption in this application.

10

11 The decryption processes described are on the basis of encryption of information by a service provider with access to
12 the secure information within multiple SPDs and the decryption of information in the target SPDs. PSOs may be
13 encrypted for a specific SPD and or multiple SPDs.

14

15 The decryption processes described also may apply to the encryption of information from an SPD to a service
16 provider. The user has no knowledge of the encryption process and usually little knowledge of the clear code being
17 encrypted. The process can be made even more secure by the service provider sending a one off encrypted encryption
18 process to the SPD. This process will have multiple applications and is referred to as the Coco method.

19

20 Standard Decryption and or Dynamic Decryption and or Recursive Decryption and or Realtime Decryption, and or
21 the Coco method may be used in any PSO in any combination determined by the service provider. The service
22 provider may always supply the required information to ensure any chosen encryption process may be reversed in
23 one or multiple target SPDs. The invention allows for any known method of encryption and or decryption to be used
24 with any part or all of the invention.

25

26 The encryption/decryption methods described pertain to communications between service provider and user. They
27 are also applicable to the secure storage of information within a UCDPS, including the encryption and storage of
28 various values in the UCDPS memory that are intermediate and or final results of processing.

29

30 The decryption and or encryption processes described for the invention may interact in any way with external
31 processes and the interaction may assist with said decryption and or said encryption.

32

33 The preferred security provided by an SPD is its function of decrypting and executing encrypted programs in secret
34 and or decrypting and processing encrypted data in secret.

35

36 The invention also allows for the decryption of information that is not securely processed.

37

38 The invention allows that the SPD may be programmed with one or multiple secure user functions and any method
39 and apparatus may be used to select the current secure user function. The system functions that perform this role are

1 referenced as system task switching functions and they allow that PSOs may be co-resident and or multitasking and
2 said multitasking may occur alongside programs that do not require the use of the invention.
3
4 The use of battery backed storage elements (and or other continuous functions, e.g. security monitoring CPU)
5 require a continuous supply of power to the device in the absence of system power. The invention allows for any
6 method and apparatus to achieve this including the integration of a battery into the device and or an external battery
7 together with suitably monitoring and switching circuitry. An A/D converter may be include to detect changes to
8 battery voltage for any reason. These are referenced as secure system power management functions.
9
10 The invention as described permits:
11 1) the secure transfer of encrypted information from an external source (including memory) using any method, to one
12 or multiple secure locations within a system CPU and or ESPD, and then (and or during)
13 2) the use of any suitable combination of microcode and or hardware and or secure internal software routines and or
14 data (that may be augmented by any other software routines and or data in any location) securely decodes this
15 encrypted information and or stores the decoded (and or remaining encrypted) information in a secure location
16 (usually internal to the device, however it may include encrypted information stored in suitable external locations),
17 and then (and or during)
18 3) the processing of sufficient information from the encrypted and or decrypted information (and or any other
19 internal and or external information that is accessible, directly and or indirectly) to enable the secure and secret use
20 of sufficient secret information that it is not practical to gain any useful benefit from any information that is in clear
21 code and said clear code may be information that was never encrypted and or information that was encrypted and
22 subsequently stored in unsecured locations, and
23 if the only reversible functional limitation applied to a software object is that which needs to be reversed by a device
24 as described for a secret processing device, permits the original software object to be used as intended, and may do
25 this without revealing part or all of the native object code constituting the software object, conditional upon the
26 appropriate information being included within the SPD.
27
28 10. Automatic Reporting Facility.
29 A major application of the SPD as it applies to the secure distribution of software objects suitable for use on a
30 UCDPS is to supply software objects that have been modified such that they must interact with the SPD on a
31 frequent enough basis, that the SPD may use this interaction to record the usage of software objects, in a manner
32 that directly and or indirectly equates to a monetary value. These modified software objects are one type of PSO as
33 described in this application and to distinguish them from other types of PSO they are subclassified as Commercial
34 Protected Software Objects or CPSO. A CPSO has some requirement for the exchange, directly or indirectly, of
35 money for the use of the CPSO. The usage of CPSOs may be time and or events based and or any other method. The
36 preferred methods allow unlimited use of these CPSOs as long as certain criteria are complied with.
37
38 As the SPD preferably does not require its host UCDPS to be attached to any remote device that may exert some
39 form of control on the use of CPSOs and as in many instances CPSOs have no intrinsic limitation on their lifespans

1 and are readily available at little or no cost, a method is required to limit the use of CPSOs such that payment is
2 made.

3

4 The invention allows for the use of CPSOs with an SPD to be controlled using any known method and apparatus
5 and this is usually on the basis of one or multiple predefined limits electronically transferred to the SPD that are
6 suitably adjusted as CPSOs are used. When the predefined limits are exceeded (and or in any other way reached) the
7 SPD preferably stops processing the CPSOs. The invention allows that said predefined limits may be granted on any
8 basis; the preferred method is to require prepayment for units. The invention does allow that there are no predefined
9 limits on the use of CPSOs, however, this would usually only apply to major account customers and even they may
10 prefer to have limits placed on what individual employees may spend. The SPD ensures that money is paid for use of
11 CPSOs.

12

13 The preferred method of controlling usage of CPSOs that permit unrestricted use of the CPSO, on the basis that the
14 SPD will record this use on any measureable units of use basis, is to prevent the SPD processing these CPSOs
15 unless there is sufficient electronic credit within the SPD and or accessible to the SPD. This electronic credit may be
16 stored in any form. The preferred method stores one or multiple values in the SPD.

17

18 11. An SPD may disable itself in part or whole when any requirements that are attached to the use of PSOs are not
19 met. This includes when PSOs have been determined as being tampered with and or it is determined that an
20 unauthorised party is attempting to use software methods to compromise the SPD and or that there is physical
21 tampering with the SPD and or that various requirements for transferring information accumulated by the SPD
22 directly and or indirectly have not been met and or that various electronic credits have been used and or that various
23 keys required to activate one or multiple PSOs have not been supplied and or are incorrect and or any other reason.

24

25 12. An SPD that is disabled in part or whole may be re-enabled in part or whole by any method including the supply
26 of an appropriately configured and validated software object.

27

28 13. Processing of Protected Software Objects by SPD: Using any suitable software routines that may be resident in
29 the SPD and or require loading from any external sources and that may require assistance from any other SPD and or
30 PSO and or external resources, the SPD responds to any suitable command generated by a software object
31 requesting access to any one or multiple functions within the SPD by determining, at any appropriate stage, that a
32 software object that has requested access to resources within the SPD is a software object that has been specially
33 prepared to work in conjunction with the SPD and that it has not been tampered with. Such a software object said
34 specially prepared is referred to as a PSO. A PSO is preferably encrypted, in part or whole, using any known one or
35 multiple encryption processes. A PSO preferably includes embedded error and or validity checking information and
36 this may use any one or multiple known methods. The process of ensuring that a software object is a valid PSO
37 preferably includes one or multiple error and validity checking processes and the decryption and or execution of
38 parts of the software object within the SPD.

39

1 If the object is not acceptable, the SPD may take any course of action including disabling part or all of the SPD,
2 reporting an error to the user using any method, denying access with no report, and or any other action. An object
3 may not be acceptable for any reason including that the object was not created for use with an SPD or that changes
4 within the software object have occurred. If the SPD receives a predetermined number and or types of errors it may
5 decide that these errors are not legitimate and take any course of action to protect the security of the device. This may
6 include granting no further access and or invalidation of part or all of the secure information within the SPD. The
7 conditions that determine this course of action may be dynamically modified by the supply of an appropriate PSO.

8

9 If it is determined that the software object is a valid software object for use with the SPD, examination of any
10 relevant part of the software object determines what action is required of the software object. Said action may
11 include performing further validity checking and or decryption and or any other actions as the PSO is processed in
12 conjunction with the SPD. Protected software objects preferably include information that identifies the type of
13 information that is included within the object, resources required of the SPD, information to assist validity and error
14 checking of the information, information to assist decryption of encrypted information and any other relevant
15 information. Said any other relevant information may be anything consistent with the resources of the SPD because
16 one feature of the SPD is its capability of being securely updated to perform any software function consistent with
17 the resources of the SPD. This updating may be dynamically performed by supplying the appropriate one or multiple
18 PSOs prior to supplying the PSO that will use the dynamically modified functions. Said PSO that will use the
19 dynamically modified functions may itself include in part or whole the information to said dynamically modify.

20

21 The following are the types of PSOs that an SPD suitable for use in the protection and distribution of software
22 objects preferably includes, however, functions for one type of PSO may be combined in part or whole with any
23 other one or multiple PSO functions to create one or multiple mixed function PSOs:

24

25 a) Secure System Update PSO: these may modify the secure system functions of the SPD using any method
26 including data and or program instructions that are to be loaded to specific locations within secure system memory
27 and or they may be programs and or data that is to be executed to perform one or multiple functions and or any other
28 method. This type of PSO is preferably heavily encrypted with multiple checksums. When validated, required action
29 is performed by the SPD.

30

31 b) Electronic Credit PSO: this adds values to one or multiple non-volatile storage locations within the SPD. Said
32 locations are preferably clear (and or any other predetermined values) when the SPD is supplied to a user for the first
33 time. Said non-volatile storage is preferably flash memory, described previously. Said values preferably equate to a
34 number of units of available credit for use with various CPSOs and or any other reason. The use of these values may
35 be for prepaid credits and these are stored in a location that is preferably decremented as available credit is used and
36 or they may be for credits that are unpaid and are effectively a credit limit against use. Any method may be used to
37 distinguish prepaid credits from unpaid credit.

38

39 c) Report Verification PSO: this verifies that a particular report generated previously by the SPD has been received
40 by the SPD. It is preferably specific to a particular SPD in that unique information within the SPD is required to

1 correctly validate and have it perform the required functions. It may perform any one or multiple functions, directly
2 and or indirectly within the SPD. It usually resets any restrictions within the SPD that are awaiting receipt of the
3 report verification PSO and may do this in any way. It also usually programs the relevant locations with a new
4 reporting interval and or modifies in any way any part or all of the report generating and verification system.

5

6 d) CPO as previously described.

7

8 Preparation of a Protected Software Object:

9 It is one object of the present invention to provide a method and apparatus for distributing a software object from a
10 producer to potential users such that a user may make as many legal and or illegal copies of the software objects and
11 distribute them as widely as they wish, however, any user executing the software object must remunerate the
12 producer and or service provider of the software object, effectively eliminating software piracy. Part of the process to
13 achieve this is to convert the original software object to a version that is modified to a PSO that is usually still
14 capable of potentially running on many UCDPs, however, those UCDPs must be equipped with a Protected CPU,
15 and for any particular PCPU that the PSO is to operate in conjunction with must meet the conditions of use attached
16 to the PSO. This may or may not require intervention by the user. In following description a reference to PCPU also
17 applies to ESPDs. The preferred method allows the user unlimited use of PSOs contingent on them having sufficient
18 electronic credit within and or securely accessible by the PCPU. The conversion from a software object to a PSO
19 preferably occurs in a secure location.

20

21 Object Support Information:

22

23 One step in the creation of a PSO is to take a software object from the producer referenced as the primary software
24 object and create Object Support Information (or OSI) that provides certain information to assist the execution of the
25 PSO. The actual creation of the OSI is usually a co-operative process between the producer and service provider,
26 however, any operations that require the use of information within the secure system memory of a PCPU would
27 usually be restricted to the service provider. The OSI is usually placed near the start of the program, however, it may
28 be located anywhere throughout the program as long as it is arranged in a sequence acceptable to the PCPU that will
29 process it, and or the PSO includes various information that may permanently and or temporarily modify the PCPU
30 such that it can locate and use the OSI. To protect the information in OSI from tampering, part or all may be
31 encrypted, and or may have various check sums that are preferably secure and or encrypted themselves. The OSI
32 may be provided in part or whole as a separate program(s) and or as part of one or more other programs and or may
33 already be present in the PCPU and or any other method. If the OSI is within separate modules and contains
34 information that the producer does not want deleted, there should be a suitably secure cross reference in the main
35 part of the PSO to check for the presence of independent modules and valid data within. The preferred embodiment
36 includes all information within the body of the primary software object one or multiple modules of the primary
37 software object. The actual method to encrypt and decrypt information may use any known method and any number
38 of levels and any combination of methods. The OSI is a description of certain functions that may be required, and
39 they may be implemented using any known method and structure. The ability to program the secure functions within

1 the target PCPU enables any new structure to be created by supplying a suitable PSO compatible with existing
2 structures.

3

4 The following is a non-exclusive list of components that may be found in OSI:

5

6 Detection of Presence of a PCPU: this is usually executed immediately after the start of PSO execution. Should a
7 PSO attempt to execute in an environment without a PCPU one or multiple adverse outcomes may result, for
8 example the hard drive may be modified.

9 The preferred embodiments of a PCPU allow access to the secure memory by the execution of various special
10 instructions. As these instructions do not exist in a normal CPU, their execution in this environment may cause
11 problems. The preferred method of ensuring that PSOs are only used in a UCDPS that has an appropriate PCPU
12 are:-

13

14 Common instruction trigger: a sequence of instructions that are common to a PCPU and the CPU that it replaces are
15 executed such that a certain combination triggers various events in the secure parts of the PCPU. The following
16 example shows one alternative:-

17 protected software loaded into memory

18 execution commences at a particular location that executes three no operation (NOP) instructions in sequence,
19 followed by a branch to the next instruction that may be the start of three more NOPs (any number, combination and
20 permutation of suitable instructions may be used)

21 the instruction following this is a branch to a routine to terminate execution of the program

22 a CPU that is not a PCPU will execute these instructions and quickly terminate the program

23 a PCPU will have the facility to recognise the particular sequence of instructions, this triggers internal routines to
24 modify the data in the branch instruction and or redirects external execution to a particular location that enables
25 continued processing of the PSO.

26 This process is transparent to the operating system.

27

28 Checking on availability of resources:

29 If the PSO is to execute in a multitasking environment where multiple tasks are concurrently executed on a time
30 sliced basis, it is possible that the PCPU has a limited number of PSOs that it can handle and the next step is usually
31 to execute a routine to determine the availability of PCPU resources and any relevant information that the PSO
32 requires to communicate with those resources; this information may be any sort of information including a reference
33 task number, and or an address or block of addresses the PSO should use to communicate with the PCPU, for
34 example the user command and data ports 199 in Figure 4, and or the amount of internal PCPU memory available to
35 the PSO and or any other information. This process may also involve the PSO providing the PCPU with certain
36 information. In the case of the PCPU described with reference to the drawings, this transfer of information would
37 usually be via the nominated addresses constituting the System Command and Data Ports in the dual port memory.

38

39 Should the PSO currently be unable to use the PCPU it can take any known course of action, the commonest of
40 which may include entering a delay routine and trying again later; an efficient method is to call a routine designed

1 for this in the operating system, with or without a message displayed. A PCPU may have the facility to transparently
2 override the operating system and a message may be displayed for the user to determine future action. Other actions
3 may include program termination, with or without a message.

4

5 A PSO preferably checks various information currently resident within the secure system memory of the PCPU for
6 the presence of certain functions within the system memory and that they are a version suitable for use by the PSO.
7 This is usually confirmed by checking that the current version number of system memory functions are current for a
8 particular PSO, however, it may use any method. Should certain functions not be current, the invention allows that a
9 PSO may be shipped with certain update information included as part of the PSO and or with other PSOs shipped
10 with the PSO, and that a PSO may automatically and or at the users direction, update the system memory functions
11 to current information and may suitably adjust the version number, and that this may be a temporary modification
12 for the duration of execution of the PSO and or a semi-permanent and or permanent change. Should the system
13 functions not be able to be updated for any reason, the PSO would usually terminate with a request for the user to
14 arrange for the necessary changes to system functions, however, it may take any other action.

15

16 Conditions of Use:

17

18 As PSOs may need to identify to the PCPU the producer of the PSO (e.g. to log usage and allocate payments), a
19 unique vendor identity code may be included in the PSO in a position and or any other way that can be determined
20 by the PCPU. This code is usually consistent on each product from the producer. The invention allows for this
21 method or any other to differentiate PSOs that are primarily commercial objects from those that provide various
22 support functions.

23

24 To differentiate a particular program from others by the same producer a unique program identity code (UPID) is
25 usually included in the PSO in a known location and or any other way that can be determined by the PCPU. This
26 may be unique amongst products from the same producer, however, it may be identical to another product by
27 another producer. This code may be further used to categorise a particular program e.g. part of the code may identify
28 the program as a game or a wordprocessor, etc., and this would usually be common across all UPIDs, another part
29 may identify the version number and the balance may be used to ensure that the UPID is unique to any others from
30 that producer. Any other relevant information may also be included in the code. The invention allows that the
31 various sub-parts of information included in this code may in part or whole be allocated their own codes.

32

33 The invention allows that the billing for the use of a PSO may use information included within the PSO. Any of the
34 following information may be located where the PCPU and or any other applicable devices or routines can identify
35 it:

36

37 Currency Identifier - this indicates the currency in which the producer of the PSO is to be paid. It is mainly used by
38 the service provider, however, it may be used for any reason.

39

1 Personal User Device Valid - this indicates whether this PSO may be used with a Personal Software Card. This is a
2 device described in another application that lets the users of one UCDPS temporarily or permanently port various
3 access and billing to another UCDPS.

4

5 Timed Basic Charge (or TBC) - is the unit rate for use of the product. The preferred rate is by the hour, however, any
6 time interval may be used. It is anticipated that users will ultimately determine the type of billing they want, and it
7 will probably be based on a time used basis associated with certain frequency discounts and possibly a cut off point
8 at which there are no additional charges. The charge rate is usually in terms of a standard unit - for example it may
9 be US Dollars. Whatever standard rate is chosen is usually standardised across PSOs. The invention allows that any
10 amount in any currency may be used. The invention also allows that the TBC for various countries may be different,
11 for example to allow for different economic conditions. Any particular PSO may include the entire set of TBCs for
12 all countries or only a subset. The TBC may not be available to all regionals. The invention allows that a discount
13 schedule may apply to the TBC for increasing use or whatever reason, and that this may vary from one region to
14 another, and this discount schedule may be stored in the PSO. Further discounting may apply for different types of
15 users, e.g. government, education, business and part or all of this information may be stored in a PSO. Various
16 vendors may wish to offer various discounts for existing customers when an updated version of their product is
17 released and or when a new product is released and these may be stored in a PSO.

18

19 The PSO usually includes one or multiple transaction processing codes to indicate the type of billing system used.
20 This may vary from region to region and each PSO may have a list that includes transaction processing codes for all
21 countries or any subset. For any particular country, there may be different codes for different groups eg, government
22 users may be billed using a different method to business, and the combinations used may vary from one region to
23 another.

24 While not an exclusive list, the following are the more common types of transaction processing codes:-

- 25 a) The PSO may be distributed at nominal cost, with the customer paying for time used.
- 26 b) The PSO may be distributed at nominal cost, with the customer paying for time used, however, a data
27 key (at no cost) is required to activate the program.
- 28 c) The PSO may be distributed at nominal cost, with the customer paying for time used, however, a data
29 key is required to activate the program and there is a charge for the key; this charge may be located in
30 the relevant fixed basic charge field.
- 31 d) The PSO may be distributed at nominal cost, however, a data key is required to activate the program
32 and there is a charge for the key, however, there are no continuing charges.
- 33 e) The PSO is only supplied on receipt of payment, with additional charges for time used. A key may be
34 required to activate the program.
- 35 f) The PSO is only supplied on receipt of payment, however, there are no additional charge.

36

37 The PSO may be one that is generic to multiple PCPUs or customised to a particular PCPU.

38

39 Event Basic Charge (or EBC) - the invention allows that usage of software may be based on the number of times the
40 program is opened and or any other event based mechanism. The Event Based Charge is the unit rate for this method

1 of billing. All of the options and or discounts and or requirements described for TBC above apply for Event Based
2 Charge and will not be repeated, however, the various combinations and particular options used may vary from the
3 TBC in any way.
4
5 Fixed Basic Charge (or FBC) - this is a fixed charge to use the software and may be a one off charge that
6 subsequently permits unlimited access on that UCDPS or a charge that grants access and then bills on a usage basis
7 using any combination of the previous methods. All of the options and or discounts and or requirements described
8 for TBC above may be applicable for Fixed Basic Charges, however, the various combinations and particular
9 options used may vary from TBC in any way.
10
11 Transaction processing codes may be constructed to detail any combination of billing processes and discounts and
12 anything else.
13
14 The ability to distribute software in massive quantities with very low upfront costs to the user may provide
15 significant changes to the methods of marketing and advertising software products. One method may be to permit
16 the user free or discounted access to various products, particularly new products. This may include various
17 promotional schedule codes (PSC) within the PSO, that may be designed to achieve any outcome that is permitted
18 by the PCPU, that the PSO executes on, and this may include codes representing anything to do with promoting any
19 sort of product using any known method, including:-
20 • a list of discounts and the time they apply may be included within the PSO, and they may be multiple. The
21 discounts may be any value, and may result in free software for variable periods of time. The facility even exists
22 for a producer to pay a user to try their product. Particular promotions may have a use by date attached to them.
23 • Another approach may be to generate a random number in the PCPU each time a program is initiated or on any
24 other basis. If this matches a code in the PSO, then various free program time may be provided on the current
25 PSO and or another program by the producer and or various prizes may be given away.
26 • The software may also be made available to a potential user with part of its functions disabled, and no charge or
27 a nominal charge applied to the use of this partially disabled program. This may be particularly useful for
28 programs that may take time to assess, for example a new accounting program, where a potential customer may
29 want to fully assess the package prior to committing to a changeover from an existing system. The activation to
30 a fully operational system may require a key (that may or may not have a charge) or simply require the user to
31 execute a program that initiates time and or event based billing, or any other method.
32
33 The information to perform any promotional function may be included in part or whole within the PSO, however, it
34 would usually rely in part or whole on secret processes within the PCPU to prevent unauthorised manipulation of the
35 promotions.
36
37 Certain software products may be unsuitable for use by particular groups. For example, certain countries may be
38 restricted from using software because of security concerns and or because it may offend certain cultures and or
39 other software may be unsuitable for children and or it may be restricted to certain professions and or it may be

1 restricted to use at certain times and or for any other reason. These are referenced as Group Restriction Codes (GRC)
2 and may be included in a particular PSO to limit access to various categories of user.

3

4 Any information included in a particular OSI may become obsolete and this may be a particular problem with prices
5 and discounts. Any information contained in a OSI may be replaced in part or whole with other more readily
6 updated information stored in any suitable location; this may include locations within the PCPU, and or various files
7 stored on one or multiple mass storage devices, and or distributed with other PSOs, and or distributed as part of
8 codes supplied to users to update PCPU credits and or any other reason, and or any other method. All of this may be
9 subject to the overall control of the service provider who can vary the actual amount charged to any particular user.
10 The billing process is described later in this application.

11

12 Part or all of the information within the OSI is usually reliant on known information within the secure system
13 memory of the PCPU to correctly interpret and or execute the various functions, however, as part or all of this PCPU
14 memory may be reprogrammed by suitably encrypted external information, part or all of which may be included
15 within the PSO, the specific requirements of a particular PSO may be met by dynamically modifying part or all of
16 the secure system memory. Additional flexibility may be gained by loading any required part of the PSO into secure
17 user memory for execution. Although various functions have been detailed for the OSI, in practice a multiplicity of
18 special functions may be included and these may occur during any part of the execution of the PSO.

19

20 Method to update the PCPU:

21 Another step in the preparation of a PSO may be to include in the PSO various routines and data that will execute
22 automatically and or under user control to update various information on the UCDPS for any reason and may
23 include:-

- 24 • update the secure system memory
25 • update various files stored on a UCDPS that contain various billing information and or discounts and or special
26 promotions and or any other information.

27 These update functions may be included as part of the actual PSO and or as part of one or more other PSOs. These
28 other PSOs may be created specifically for the purpose and or may be parts of other PSO applications. These other
29 PSOs may be supplied to the user with the said actual PSO and or may be supplied separately.

30

31 Error and Validity Checking:

32 A PSO, and the PCPU with which it is to operate, are provided with a number of secure mechanisms to protect
33 against unauthorised analysis of information stored within. As there may be considerable financial gain to any party
34 that manages to compromise the security of either, it is anticipated that a number of attempts will be made to
35 compromise the security of both, and one method may be aimed at changing various parts of the PSO in an attempt
36 to analyse the various outcomes. In order to protect against this and also to detect genuine errors in the PSO, it is
37 usual to use one or more error and or validity checking processes on information within the PSO, and these may use
38 any known method and apparatus, and these may be dependent in part or whole on functions within the PCPU, that
39 may include:-

- 40 • routines within system memory, and or

1 • various algorithms implemented in hardware within the PCPU, and or
2 • routines loaded from external sources (usually, in part or whole, in encrypted format), and or
3 • loaded from the PSO (usually, in part or whole, in encrypted format), and or
4 • any other source.

5 The error checking and validity checking is a process that usually occurs in total secrecy at both ends, with the
6 service provider the only party that knows the process. The service provider is aware of the processes available in
7 any particular PCPU to extract and validate any parity information and or CRC information and or any other
8 information, and the method used to take the actual code of the PSO and generate the expected parity information
9 and CRC information and any other information, and the methods to determine whether or not the expected
10 information matches the extracted information. The service provider can take a PSO at any stage or stages in the
11 conversion process from software object to PSO and analyse the information and add and or change data in such a
12 manner that the outcome when run through the error and validity checking process in the PCPU will not detect any
13 errors. Should one or multiple parts of the PSO be changed by an unauthorised party, then the error and or validity
14 checking process in the PCPU will detect the modifications and may take any known action, including those actions
15 described later. If the service provider prepares a PSO for error and validity checks and the process complements a
16 protocol preprogrammed into the PCPU, there may be no need for any other additional information within the SPO,
17 however, if the service provider follows a variable pattern and or non-standard processes then additional information
18 may need to be included within the PSO to permit correct analysis at the other end, and this may use any known
19 method. As part or all of the PSO will usually be subsequently encrypted, there is no practical way for an external
20 analysis of the PSO to even hint at which apparently meaningless data is part of error/validity checking and which is
21 encrypted information. Furthermore, the error/validity checking information may itself be encrypted. Furthermore
22 the system usually only needs to work in one direction - provider to user, although some processes may need to be
23 included within the PCPU to generate error and or validity checks on information that is to be stored in encrypted
24 format in external resources (these are discussed in more detail in the applications dealing with these devices). Any
25 number of error detection and validity checking processes may be applied and these may occur during various levels
26 of the encryption process. The invention also allows that error and or validity checking may be performed on part or
27 all of the PSO with the actual method to reverse this included within the PSO, and as long as part or all of the
28 method to reverse is encrypted and the reversal process occurs in secrecy, there is no means of reverse engineering
29 the process, and the actual methods and or apparatus used may be any known method and or apparatus.

30
31 Encryption of the information to create the Protected Software Object:

32 The final step in the creation of a PSO is the conversion of the software object as supplied by the producer together
33 with any additional information as previously discussed to a protected program that provides the security against
34 illegal use of the program. By encrypting the PSO using any known encryption method and any combination of
35 known encryption methods, including the processes described previously, the software object is converted to a PSO
36 that in part or whole may only be executed internal to an appropriate PCPU. The software object may be encoded to
37 one and or multiple levels of complexity. The software object is preferably analysed to determine which parts require
38 encryption, what method or methods of encryption should be applied and any ancillary information that is required
39 to support these methods. The actual arrangement of information within any part of the PSO to effect various

1 outcomes will be highly variable with the exception of certain functions fixed by a particular PCPU, and as the
2 present invention allows for the provider supplied PSO to be flexible and the functions within a particular PCPU to
3 be programmed in a multiplicity of ways, the various combinations and permutations to achieve the same outcome
4 are obvious, once the specific requirements and one method of achieving this are described.

5

6 Crediting funds into a PCPU (and or other PCPU):

7 The present invention allows that a part of the secure system memory of a PCPU may be securely programmed with
8 information that indicates an amount of credit (using any method and or currency) that may be offset against
9 software usage (and or any other applicable uses). Various secure locations within the PCPU within a particular
10 UCDPS may contain codes that are unique to that particular PCPU and these codes are usually secret. A particular
11 PCPU usually has a publicly accessible electronic signature that can be used to identify a particular UCDPS. A
12 particular PCPU may also have other characteristics that are unique to a particular PCPU, for example, particular
13 software routines and or encryption/decryption processes and or any other applicable variation. Because of the secure
14 nature of information contained within a PCPU, it is preferable that conversion of a software object into a PSO is
15 performed by a service provider, and that the actual information within PCPUs is maintained in a secure
16 environment. When a UCDPS is initially shipped to a customer, it is likely that the PCPU has no credit value
17 programmed within and may not be activated to execute PSOs. The process of activating a particular PCPU may be
18 accomplished by any method and apparatus, including:

19 1) The user contacts a service provider (using any method, the most convenient usually being via a modem) and
20 supplies the service provider with the serial number of the PCPU, the amount of credit required, and payment details
21 (that is preferably a credit card payment) that may use any known method.

22 2) Using known details about various information within that particular PCPU, the service provider uses the
23 requested amount of credit and encrypts this amount using any known method and apparatus (and an experienced
24 person should be able to devise multiple techniques based on the encryption/decryption processes described earlier).
25 The encryption process that may use any information (including time and or date and or any other unique and or
26 global information within the PCPU and or that may be securely transferred to the PCPU, using any known method
27 including those described in this application) to generates a one time code that may be decrypted within the PCPU.

28 3) The one time code is transferred to the user of the PCPU and entered into the computer. The code is decrypted. If
29 an error is generated, the user may be advised. Once the amount is confirmed the nominated credit is programmed
30 into any appropriate secure non-volatile location internal to the PCPU that cannot be tampered with.

31 4) This process may activate the PCPU if required, however, the preferred determinant as to whether or not a
32 particular PCPU will execute one or multiple PSOs is based on the amount of available credit.

33 5) The available credit is progressively decremented as various PSOs are used, and the present invention allows for
34 any method and apparatus for billing for PSO use.

35 6) Software usage of various software objects may be logged. This is described later.

36 7) When the credit amount is decremented to a predetermined amount (and said predetermined may be by the
37 service provider and or the user) the user is advised that additional credit will be required shortly. The method of
38 advising the user of an imminent shortage of credit may use any method and or apparatus, however, as the programs
39 that implement this process are preferably executing in part or whole from within secure memory internal to the
40 PCPU, the facility exists to generate an internal interrupt and jump to an appropriate internal and or external

1 program. This may occur at any time, with the most usual being shortly after a system reset. The process may be
2 transparent to the operating system. The facility exists, using a similar process (and or any other method and or
3 apparatus) for the user to generate a current report of available credit and or software object use.
4 8) For the second and subsequent contacts with a service provider to refresh the credit available within the PCPU, in
5 addition to providing the service provider with the electronic signature of their PCPU, the user will usually be
6 required to advise the service provider of a code (that is securely generated within the PCPU using any known
7 method and apparatus within the PCPU) that may include current information on remaining credit (that may be
8 zero) and may include information on the usage of part or all software objects that have been used in the period.
9 9) Step 2 is repeated, however, in addition to credit information, the code supplied to the user usually contains an
10 encrypted message that informs one or multiple routines within the PCPU that information pertaining to software
11 object use has been received by the service provider. Storage locations allocated to this information may then be
12 cleared.

13

14 The present invention allows that although the process as described requires prepayment for services, the process is
15 also compatible with the provision of credit within the PCPU on account terms with selected users, and the credit
16 amount allocated would usually be sufficient to cover expected usage (or may be any amount). The actual amount to
17 bill the user may be calculated by subtracting the amount of credit remaining from the amount supplied in the
18 previous period and or any other method and apparatus.

19

20 A user friendly menu system may be used to assist part or all of the process described above.

21

22 Monitoring the use of protected software objects:

23 The present invention allows for any known method and apparatus that can monitor and or record the usage of
24 PSOs (and or software objects), and preferably one that is compatible with multitasking programs in a single
25 processor and or multiprocessor environment, and preferably one that provides a tamperproof, secure system that
26 operates in part or whole from within a PCPU and or any other SPD, when the UCDPS is an independent entity, and
27 or when independent and connected to a network and or when independent and connected to Internet or similar, for
28 its correct functioning, and or when the UCDPS is dependent in part or whole on connection to a network, and or is
29 dependent in part or whole on connection to the Internet (or similar). In a single task UCDPS the SPD usually starts
30 recording usage when activated and terminates when the PSO finishes. The preferred method in a multitasking
31 environment where usage is timed is to generate an internal interrupt within secure microprocessor on a periodic
32 basis, and said interrupt activates a routine within internal secure memory that retrieves the contents of the program
33 counter of the system microprocessor at the time of the interrupt and compare this with an address map generated by
34 the PSO to determine which program was executing during the interrupt. The invention allows for any combination
35 and or permutation and or weighting for usage of any one or multiple PSOs. Event usage may only require counting
36 occurrences of the measured event in single and multitasking UCDPS. The usage of PSOs is usually recorded in part
37 or whole within secure internal memory, however, the invention allows that part or all of the information on the use
38 of PSOs may be encrypted and stored external to the PCPU and or UCDPS. It is preferable to keep sufficient
39 information on PSO use internal to the device, in order that a software vendor receives the appropriate payment in
40 the event that external storage of this information is corrupted, in which case while there may be no detailed

1 breakdown of transactions, the vendor is correctly remunerated. The aforementioned processes are transparent to the
2 operating system. An alternative non transparent method is to have the operating system perform various routines
3 during task switching that may activate various processes within the secure internal memory to record details about
4 program execution. Information on program usage is usually maintained in secure non-volatile storage locations
5 internal to the SPD. The invention allows that a report on software usage may be prepared (usually in encrypted
6 form, using any method and apparatus) for transmission to a service provider and or any other authorised party on a
7 periodic basis, that may be any period and may be fixed and or variable; this report is usually generated by secure
8 routines within one or more PCPUs from information that may be internal and or external to the PCPU.

9

10 Controlling execution (and or any other processing) of protected software objects:

11 One objective of the invention is to provide a method and apparatus that may be used to protect software objects in a
12 manner that does not restrict the copying of the PSO and that in the preferred scenario, would provide at nominal
13 cost, a copy of that particular software object to any user of a UCDPS requiring it. An optimal situation would be the
14 collation of all PSOs suitable for use with a particular type of UCDPS onto a collection of CD ROMs that may be
15 supplied to users at nominal cost. Update CD ROMs may be made available on a periodic basis. The invention
16 allows for PSOs to be supplied on any medium and this may include access to a database of PSOs via the Internet.
17 The capacity of a SPD to decrypt externally supplied information in a secure manner that may include realtime
18 decryption and decryption using software routines within internal secure memory (that may be supported by
19 hardware decryption engines) together with the method and apparatus to securely encrypt information for transfer to
20 a service provider (or any other appropriate external party), provides a secure and flexible environment for restricting
21 the use of a PSO using multiple methods and the invention allows for all of these. At some point in the processing of
22 a PSO, and usually at the commencement, the SPD may requires certain information from the PSO of relevance to
23 determining the type of protection system applied to the PSO, for example, certain data (or any other method) may
24 be extracted from the PSO to inform the SPD that this particular PSO may be executed on a time used basis and
25 whether or not this is linked to the availability of credit within the SPD. Information on the vendor and or the
26 product code of the PSO and usually the amount to charge for a unit of execution time may then be required (and
27 this information may be required for any other protection systems). One source of this information is the PSO itself
28 and this information may be extracted by the SPD, using any method and apparatus. The usual process extracts
29 (using any method and apparatus) the vendor and product code from encrypted parts of the PSO and stores it within
30 secure memory internal to the SPD. The cost of executing (and or any other processing) the PSO on a time and or
31 event basis and or any other basis is extracted from the PSO where applicable. Where the known art grants a distinct
32 right to execute a particular program, the SPD grants a generic right to execute as long as certain internal and or
33 external generic codes match the requirements of one or multiple PSOs. The invention allows that information
34 contained within a PSO may not be current as regards execution costs (and or any other information) and provides
35 for any method and apparatus to compensate for this, with the preferred method being the provision of one or
36 multiple files located on a suitable mass storage device attached directly and or indirectly to the UCDPS, with said
37 files referenced in this document as Current Data Files (or CDF). CDF may be updated as required using any
38 method and apparatus (including automatic update using information contained in newly released PSOs). A current
39 data file may contain any information, and may replace part at least of that within a PSO, however, it will usually
40 include details of the costs associated with executing PSOs (that may be all, or a subset of, the available PSOs), and

1 this may include information on discounts for frequency and or quantity and or special groups and or special
2 promotions and or any other information. A CDF may have a creation date and or one or multiple blocks of
3 information pertaining to one or multiple PSOs may include the date (or any other method and apparatus to effect
4 an equivalent result) said information pertaining, became valid. When a PSO is created, the date of creation (and or
5 any other method and apparatus to effect an equivalent result) is usually included within the PSO and when a PSO
6 is processed, the date within the PSO may be compared to that within the CDF (if present), with the more recent
7 information preferably used. The information within a CDF is preferably encrypted and this may be for any reason,
8 including protection against tampering with the information. Various validity checks may be performed when
9 information within a CDF is loaded and or used (this may be for any reason including detecting unauthorised
10 alterations to the information). When an SPD generates a report for the service provider (or any other authorised
11 party) it may include information on the currency of information within a particular CDF, and or the absence of a
12 CDF, and or the creation dates of the PSOs executed. It may be that a user knows that access to a particular CDF by
13 the SPD may result in increased costs to the user than would be incurred, by referencing the billing information in
14 the actual PSO, and said user may be reluctant to update their current CDF and or may delete the CDF (the
15 invention allows that the presence of at least one CDF is required). The invention allows for any method and
16 apparatus that may be used to circumvent this potential problem, including the service provider adjusting billing to
17 reflect current charges (or any other reason).

18

19 The preferred protection system is applicable to PSOs that are permitted to operate within a UCDPS on an
20 unrestricted basis, as long as certain criteria are met:

- 21 • the PCPU and or any other PCPU has sufficient credit programmed into the device (using any method and
22 apparatus) to cover the costs incurred by the user in executing the PSO, and or
- 23 • the use of each PSO is logged and this may be time based and or event based and or any other method and
24 apparatus that requires periodic reports on software use and or any other information to be provided to an
25 appropriate external party.

26

27 The invention allows that PSOs may be used on a time and or events basis and that this may require the availability
28 of credit within the SPD and or may not require the availability of said credit, in which case the user would usually
29 be billed for use of software after providing a periodic report to the service provider. As the PSO is used, the
30 appropriate units of usage (that may be time and or monetary and or any other token) are progressively adjusted
31 against a particular vendor/product code (and or any other method). When available credit is progressively utilised
32 in association with the use of one or multiple PSOs, the amount of available credit to the user is decremented. The
33 credit units within a SPD may represent any token and or currency, using any method. The invention allows for any
34 method and apparatus to securely store this information and this may be internal and or external to the SPD. A
35 number of method steps were described earlier for transferring credit to a particular SPD, and a similar method is
36 used for supplying a service provider with information about PSO usage, and for the service provider to inform the
37 SPD that this information has been received, and that further use of PSOs may continue, however any other method
38 and apparatus is allowed for. For PSOs that require the availability of credit within the SPD for continued operation,
39 a user may be required to provide a report when available credit within the SPD is zero and or some other
40 predetermined amount and or the user may be required to report information to the service provider on a periodic

1 basis, and said periodic basis may be any period and it may be varied by the service provider, and or the user may be
2 required to report to the service provider when a certain number of events have occurred, that may be any
3 combination of events, including the number of times one or multiple PSOs have been used, and or a user may be
4 required to provide a report to any authorised party for any reason; those PSOs that do not require the presence of
5 available credit within the SPD may share any of the reporting requirements discussed, however, they usually are
6 independent as to the state of credit within the SPD. In practice a mix of methods may be used and a periodic report
7 may be required. When a report is required on a periodic basis, a secure battery backed realtime clock/calendar is
8 the preferred source of determining (in conjunction with predetermined and or otherwise information on the time
9 intervals to be used) when the relevant time interval has occurred. When available credit expires and or a certain
10 date and or time is reached and or a certain number of events and or type of events have occurred, part or all of the
11 functions of the SPD may be disabled.

12 Whatever the trigger point for requiring the user to supply the service provider with a report generated by secure
13 methods within and or in conjunction with the SPD, the method steps to supply said report and to reactivate the SPD
14 for further use may use any method and apparatus, including:

15 1) When the SPD determines that internal and or external information is due for reporting to a service provider, any
16 method may be used to alert the user, and one preferred method uses the ability of the PCPU to call routines
17 transparently to the operating system by having the secure microprocessor DMA information to display memory and
18 this facility may be used to overlay a message on the display device of the UCDPS advising them to execute a
19 program that will generate a report and this is preferably at the start of a processing session.

20 2) The report generator is executed and this may display a menu based system to assist the user through the process.
21 If information is to be transmitted to the service provider via a modem and any return information received by the
22 same method then the process may be fully automated and transparent to the user. The invention allows for any
23 method and apparatus that assists the user with the process. The report generator usually triggers routines within the
24 SPD that collate and encrypt the information to be supplied to the service provider, with the information usually
25 including one or multiple unique identity codes for a particular SPD, and this may and or may not be encrypted. The
26 report would usually be integrated with any information to be supplied to a service provider as regards credit
27 remaining within a SPD.

28 3) The user contacts a service provider (using any method, the most convenient usually being via a modem) and
29 supplies the service provider with the information generated by the report generator. As mentioned, if using a
30 modem this process may have minimal user intervention. If a modem is not available the information may be sent by
31 any method, including as a file on a diskette and or the information may be read over a telephone (this may be verbal
32 or use the numeric pad) and or any other method.

33 4) On receipt of the information the service provider determines the electronic signature of the SPD generating the
34 report and using known details about various information within that particular SPD decrypts the report and
35 confirms that it has not been tampered with.

36 5) Any method may be used to collect payment for any amounts payable as a result of use of software objects and or
37 any other reason.

38 6) The service provider prepares a one time code using any method and apparatus that may be correctly interpreted
39 by the target SPD and is usually specific to a particular SPD.

1 7) The one time code is transferred to the user of the SPD and entered into the computer. The code is decrypted. If an
2 error is generated the user may be advised. The purpose of this information is usually to advise routines within the
3 SPD that a correctly encoded report was received by the service provider and that further use of PSOs may proceed.
4 Other information, e.g. credit may be included with said one time code. The normal process preferably provides a
5 report and ensure continued use of PSOs prior to the expiry date of the current period.
6
7 With the exception of the periodic updating of internal credits and the reporting of software usage the method and
8 apparatus of software protection and distribution may be transparent to the user. As long as payments are made as
9 required the user would treat a PSO as they would any presently available software object.
10
11 The invention allows that a user may purchase a particular PSO for unlimited use, and this may use any method and
12 apparatus, including debiting the cost of the PSO from any available internal credit and setting a code such that
13 there is no further billing for use of this PSO; one method allows for a file to be kept on a suitable mass storage
14 device attached directly and or indirectly to the UCDPS (referenced as Exempt PSO File, or EPF) and this may store,
15 usually in encrypted format (in part or whole), a vendor code and product code and a code that is unique to a
16 particular PCPU for that particular product. Said code is usually created when payment is made and this may be
17 automatic when there is available credit in the PCPU and or may be supplied by the service provider on receipt of
18 payment and or any other method. When a PSO is loaded for execution, routines within the PCPU may access this
19 file and determine whether or not a particular PSO that is normally charged on any type of usage basis, is exempt
20 from this process. One alternative is for the service provider to credit any debits made for use of prepaid PSOs.
21
22 A variation on the method and apparatus described earlier allows for a certain group of programs to be used on an
23 unlimited basis for a period of time, for one fixed charge. This may apply to computer games for example that may
24 be used for \$X per month, where X may be any amount. A periodic report is required to determine usage of the
25 different games in order to appropriately pay the vendors of those games. The actual pro rata allocation to various
26 vendors may be made by the service provider using any agreed formular. This may use a special code within the
27 PSO and or the CDF and or the EPF and or any other method. The invention allows that multiple software object
28 groupings may use this variation and the amount charged for one grouping may be the same and or different to other
29 groupings.
30
31 The invention allows that part or all of the processes that require the user to supply one or multiple codes to activate
32 part or all of the invention for any reason, may use any method and apparatus to prevent attempts at creating said
33 codes by trial and error and or any other method, with the preferred said method and apparatus to prevent, being a
34 routine(s) within secure internal memory that log in non-volatile storage invalid attempts at entering codes and part
35 or all of this information may be stored in one or multiple external files, that may be directly and or indirectly
36 attached to the UCDPS. The invention allows for any action to be taken including, disabling the PSO and or
37 multiple PSOs and or the PCPU and or all processing capability, and this may be done using any method and
38 apparatus.
39

1 The invention allows that a user who has purchased in part or whole one or multiple PSOs and or earned frequency
2 discounts on one or multiple PSOs and or any other reason, may wish to port these to another SPD for any reason,
3 including that the user has purchased a new machine and or because the user wishes to sell part or all of any interest
4 in one or multiple PSOs to another user. The invention also allows that one or multiple PSOs may not offer this
5 facility. The invention allows that there are multiple known methods and apparatus for achieving this including, the
6 preferred option that may involve the following method steps:
7 1) the user activates a program to reverse various capabilities granted to a particular SPD, for example activation
8 codes and or discount schedules. This would usually initiate a menu type screen on the display device, using the
9 method previously described, of the UCDPS to assist the process.
10 2) the user nominates those PSOs that are to have part or all rights of use transferred to another SPD.
11 3) the program may change various internal locations and may change various external locations such that existing
12 rights are no longer valid on the SPD.
13 4) encrypted information is supplied to the service provider indicating that various access rights to one or multiple
14 PSOs have been modified, and the encrypted information (using any method and apparatus) is decrypted and
15 verified for validity, using any method and or apparatus.
16 5) the user usually informs the service provider of the new SPD that various access rights are to be transferred to.
17 This may be multiple SPDs.
18 6) any codes and or discounts and or new versions of encrypted PSOs are prepared for the nominated PSOs and
19 supplied accordingly.

20

21 User Password:

22 Certain information is preprogrammed into the PCPU prior to being made available to a user and some of this may
23 restrict the user of that particular PCPU from various functions available within the PCPU and or available in
24 various information supplied by a service provider. An example may to restrict users of a particular country from
25 various services. The invention allows that some of these restrictions may be reprogrammable with information
26 supplied by the service provider while other information may be fixed. A user of a UCDPS equipped with a PCPU
27 may have various restrictions that they want placed on the use of the PCPU and these would normally be
28 programmable by the user, and these may included any approved functions, using any known method. A user may
29 want a master password for themselves and this would usually be stored within non-volatile storage elements of
30 system memory, and the correct entry of this may be required to activate the PCPU (in the case of a PCPU the CPUs
31 within may be disabled). Additional passwords may also be required that allow limited access to the PCPU, for
32 example, certain passwords may be attached to children to prevent them from using unsuitable software, or certain
33 employees may be prevented from playing games on their computers during business hours. Certain functions may
34 also be attached to various passwords, e.g. to monitor usage.

35

36 Any program and or data that is preprogrammed into a PCPU may in part or whole be the same as those within
37 other PCPUs and or may in part or whole be unique to other PCPUs. Any program that is currently within secure
38 memory may call on any currently external programs and or data and or apparatus to assist the functions of said any
39 program.

40

1 Protection of other forms of information:

2 The present invention also allows for the inclusion of part or all of the method and apparatus described in this
3 application when used in conjunction (in any manner) with any secure apparatus (that may be one or multiple
4 devices) for use in:

5 the secure decoding of encrypted (in part or whole) video information and or any other encrypted (in part or whole)
6 visual information, and or the secure generation of the necessary signals to display the decoded information on a
7 suitable visual output device, with said necessary signals preferably constrained within a secure location within said
8 visual output device and or

9 the secure decoding of encrypted (in part or whole) sound information and or the secure creation from this decoded
10 information of the necessary signals to drive a loudspeaker (and or equivalent), with said necessary signals
11 preferably constrained within said loudspeaker (or equivalent) and or

12 the secure decoding of encrypted (in part or whole) text as may be the case with electronic books and or newspapers
13 (and or any other printed matter of commercial value that is published in electronic form) and the secure generation
14 of the necessary signals to display the decoded information on a suitable visual output device;

15 this particularly applies when said secure apparatus securely monitors and or logs (directly and or indirectly) the use
16 of the encrypted information as it is decoded and used within said secure apparatus, and or
17 that includes (directly and or indirectly) one or multiple methods and apparatus to ensure payment is made for said
18 use.

19 Any combination of software and or hardware and or microcode may be used to implement the method and
20 apparatus, with the preferred method and apparatus:

21 retrieving pricing information from the encrypted information; and or

22 timing the use (and or counting the frequency of use) of said encrypted information; and or

23 storing this within the secure apparatus (that may include secure locations external to the secure apparatus) in non-
24 volatile storage elements; and or

25 debiting an amount of electronic funds previously embedded within the secure apparatus; and or

26 recording an amount to charge at a future date; and or

27 generating a report of usage (preferably with a breakdown for each vendor and or product) that is supplied to the
28 information provider (and or agent); and or a

29 system to ensure that said report of usage has been received by the relevant parties; and or

30 that may disable part or all of its capabilities in the event that electronic funds expire and or internal credit limits are
31 exceeded and or a report is not provided to the relevant parties and or that periodic information is not received from
32 said relevant parties; and or

33 that may be updated with additional electronic funds and or any previously used (or expired) credit limits reset. The
34 encrypted information may be supplied on any machine readable physical media (e.g. CDROM or Videodisc) and or
35 broadcast using any method.

36

37 When an external PSO requires to access the SPD, the normal process is to:

38 a) block interrupts if required and write a command to the system command input port requesting use of the SPD.

39 b) the process of writing to the port preferably generates an interrupt so there is a rapid response from the secure
40 microprocessor, otherwise there may be a delay while it is polled.

- 1 c) the secure microprocessor writes to the system command output port a value that indicates if there are currently no
2 resources and another value if there are resources, together with the address and size of a user command input and
3 output port and a user data input and output port. It clears the value written by the system microprocessor into the
4 system command input port.
- 5 d) the PSO reads the information from the system command output port and reactivates interrupts.
- 6 e) if resources are currently unavailable to the PSO it may enter any known delay routine and try again later. The
7 option exists for it to branch to a routine to advise the user that the multitasking capability of the UCDPS is currently
8 fully extended.
- 9 f) if granted access it saves the appropriate user port information in an accessible location and may read and write to
10 these ports as required. There is no need to disable interrupts when accessing the user ports allocated to it. There is
11 no requirement to modify the task switching routines of the UCDPS operating system.
- 12 g) if the SPD has granted a PSO access to the SPD then it preferably stores relevant information about the PSO user
13 partition in a known location in the system partition, usually with information on other user partitions.
- 14 h) the SPD waits until the PSO starts writing information to its user data input port, this may be triggered by an
15 interrupt or polling of locations and or any other method.
- 16 i) the SPD transfers the information into the allocated secure user partition. This may be done via the user data input
17 port and or via Direct Memory Access (DMA) or by direct programmed I/O by the secure microprocessor and or
18 any other method permitted by a particular embodiment of the invention.
- 19 j) PSOs usually include various information to assist the SPD in addition to various encryption and validity checking
20 information.
- 21 k) various system functions are activated to decrypt and validate where appropriate and extract other information
22 relevant to the PSO.
- 23 m) the PSO may be determined to be a valid System Support Object that is required to be loaded into the secure
24 system partition to addresses determined by any method. The system Support Object may include data and
25 commands as to what sort of processing is required and or it may contain executable instructions, in which case the
26 secure microprocessor will be directed to execute this program.

27

28 This is usually granted if the SPD currently has sufficient resources. This would normally be the case in a single
29 tasking system, however, in a multitasking environment, an PSO may need to wait. Said wait may use any method.

30

31

32

33

34

35

36

37

38

39

40

1 The claims defining the invention are as follows:

2 1. A method of distributing software objects from a producer to a potential user comprising the method steps of:

3

4 equipping a user controlled data processing system with a secret processing device, and said user controlled data
5 processing system equipped with said secret processing device is referred to as a PUCDPS, wherein said secret
6 processing device of said PUCDPS may be configured to be dependent in part or whole on the coupling of said
7 PUCDPS for part or all of the time, to one or multiple remote computers and or any other data processing devices,
8 however, part or all of said secret processing device may operate and or be configured to operate in a stand alone
9 PUCDPS and may remain operational for extended periods after said PUCDPS is removed from a source of power
10 one or multiple times, and or moved to different locations, and or reset one or multiple times, and or any other event
11 that would normally disrupt processing on said PUCDPS;

12

13 providing one or multiple service providers, with part at least of secret information within one or multiple said secret
14 processing device that is required to provide part at least of the services required by one or multiple said PUCDPS,
15 wherein said service providers are the agents of said producer;

16

17 providing a software object;

18

19 modifying part or all of said software object such that it is functionally limited to require said PUCDPS for correct
20 processing (in this claim execution and process and processing are interchangeable and refer to execution of
21 instructions and or processing of data) and the functional limitation may be Oscar compatible and or may be
22 Groover compatible and or may use any encryption method able to be reversed in said secret processing device,
23 furthermore, said functional limitation may be of one or multiple essential parts of the software object such that it is
24 *not practical* to regenerate the original software object from any parts that are not functionally limited, and for any
25 particular functionally limited software object the functional limitation may only be reversed in part or whole by a
26 specific said secret processing device with unique characteristics necessary to reverse the functional limitation, or
27 the functional limitation may be reversed in part or whole on a plurality of said secret processing device identified by
28 common characteristics necessary to reverse the functional limitation; and or

29 modifying part or all of said software object, using any method, such that said software object is securely linked in
30 part or whole, using any method, to any one or multiple conditions of use, that in part or whole are not practical to
31 tamper with and said conditions of use may include any code that identifies the producer of said software object and
32 or identifies said software object in any way, such that when said secret processing device is used to reverse part or
33 all of said functional limitation, said secret processing device may record use of said software object and or the use
34 of software objects of a particular producer and or any other record that in part or whole is used in determining
35 remuneration to the producer and or any other parties and or said conditions of use includes any code that contains
36 information which may be used by the SPD to determine if said software object:

37 is permitted to execute and or process in part or whole on a units of time used basis, and may include what fee
38 should be applied for the use of said software object and said fee may be any unit of measurement and is
39 preferably a generic units of use basis and said generic units may be attributed any real currency value at any
40 stage; and or

1 is permitted to execute and or process in part or whole on an events occurring basis, for example the number of
2 times one or multiple parts of said software object are loaded and or executed and or any other measurable
3 events basis, and may include what fee should be applied for the use of said software object and said fee may be
4 any unit of measurement and is preferably a generic units of use basis and said generic units may be attributed
5 any real currency value at any stage; and or
6 is permitted to execute and or process on an unlimited basis subject to a fee, and may include what fee should
7 be applied for the use of said software object and said fee may be any unit of measurement and is preferably a
8 generic units of use basis and said generic units may be attributed any real currency value at any stage; and or
9 is permitted to execute and or process on any type of limited basis subject to a fee, and may include what fee
10 should be applied for the use of said software object and said fee may be any unit of measurement and is
11 preferably a generic units of use basis and said generic units may be attributed any real currency value at any
12 stage; and or
13 requires entry of one or multiple data keys of any type prior to initiating use of part or all of said software object
14 for the first and or any other time on a particular said secret processing device and may include whether or not a
15 fee is to be charged; and or
16 requires any other restrictions of any type to be placed on use of said software object ; and
17 any said software object modified in part or whole as described is referred to as a Protected Software Object;
18
19 providing one or multiple protected software object onto computer-accessible memory media and or any suitable
20 apparatus for electronically transferring said protected software object to a potential user, and preferably the
21 conditions of use attached to said one or multiple protected software object permit said protected software object to
22 be used on a time used basis in a PUCDPS with a secret processing device that has sufficient quantity of one or
23 multiple said unit of measurement stored within and or securely accessible;
24
25 shipping said one or multiple said protected software object on said computer-accessible memory media to a
26 potential user and or said electronically transferring said one or multiple protected software object;
27
28
29 loading said one or multiple said protected software object into said PUCDPS and executing as permitted by said
30 conditions of use;
31
32 where required by said conditions of use, a user friendly menu system and or any other method provides for the user
33 to:
34 request the supply of one or multiple said unit of measurement that may be required by the said secret
35 processing device for any purpose, and or
36 receive one or multiple said unit of measurement, preferably in suitably encrypted format, that may use any
37 method, and transfer said unit of measurement into the said secret processing device, and or accessible to the
38 secret processing device, and or
39 request the supply of one or multiple data keys that may be required by the said secret processing device, and or

1 receive one or multiple data keys and transfer said data keys into the said secret processing device, and or
2 accessible to said secret processing device, using any method, and or
3 generate one or multiple reports of software usage and or any other information that may be required, and
4 supply said reports to said service provider and or any other external location, as required, and or
5 receive one or multiple codes confirming that said report has been received and supply said one or multiple
6 codes confirming into said secret processing device and or accessible to said secret processing device, and or
7 request the service provider and or any other authorised party for one or multiple codes that may be used to
8 reactivate part or all of said secret processing device that may have been disabled for any reason, and or
9 receive one or multiple codes to reactivate part or all of said secret processing device that may have been
10 disabled for any reason and transfer said codes into said secret processing device, and or accessible to said
11 secret processing device, and or
12 for any of the preceding, the information generated by said PUCDPS and or received from said service provider is
13 preferably transferred electronically, however, any other combination of methods may be used including mailing of
14 computer-accessible memory media containing the information.
15
16 2. A method of distributing software objects according to Claim 1, wherein said secret processing device may:
17
18 securely decrypt and execute (in this claim execution and process and processing are interchangeable and refer to
19 execution of instructions and or processing of data) and or process instructions and or securely decrypt and process
20 data; and or
21
22 securely decrypt and execute and or process instructions and or securely decrypt and process data that complies with
23 part or all of the requirements of reversing functional limitations applied that are said Oscar compatible; and or
24
25 reverse any functional limitations applied that are said Groover compatible; and or
26
27 reverse part or all any functional limitations applying to said protected software object; and or
28
29 may decide to reverse one or multiple said functional limitations applied to one or multiple said protected software
30 objects, based on the said conditions of use said securely linked to said protected software objects, where said decide
31 is an autonomous decision, based in part at least, on secure processing of information internal and or external to said
32 secret processing device, and that as long as said the requirements of one or multiple said protected software objects
33 and or said secret processing device are complied with, the user of a said PUCDPS is able to execute and or process
34 one or multiple said protected software object on the same basis as if they were said software object; and or
35
36 transfer into said secret processing device and or have transferred any part of one or multiple information that may
37 be necessary to provide any of the functions required by said protected software object; and or
38
39 access any information that may be located external to said secret processing device in order to provide any of the
40 functions required by said protected software object; and or

1
2 examine said conditions of use said securely linked to said protected software object; and or
3
4 determine a response to said conditions of use, and or
5
6 respond to said conditions of use; and or
7
8 provide one or multiple area of secure memory that is not practical to analyse; and or
9
10 provide for partition of secure memory into one or multiple secure system partitions and one or multiple user
11 partitions whereby programs in said system partitions may access said user partitions, however, said user partition
12 may not access said system partition unless authorised, and or any particular said user partition may not access any
13 other said user partition unless authorised; and or
14
15 may transfer part or all any one or multiple said protected software object and or any other software objects from
16 unsecure to said secure locations for processing and or transfer any information from said secure location to said
17 unsecure location; and or
18
19 may securely decrypt part or all of decrypted parts of said protected software object and or any other encrypted
20 information within said secure locations; and or
21
22 may process part or all of one or multiple said protected software object in secrecy, including processing of part or
23 all of that information loaded in encrypted format and decrypted; and or
24
25 have the capacity to detect whether part or all of said protected software object have been tampered with; and or
26
27 handle the requirements of a large number of different protected software objects that it has not been specifically
28 preconfigured for while in unsecure locations; and or
29
30 may perform secret encryption and or secret decryption in a manner that cannot be analysed, and this may be a
31 software and or hardware function; and or
32
33 have the capacity to implement in part or whole, one or multiple hardware devices in programmable logic and
34 preferably programmable logic that may be rapidly erased in the event of tampering, and this includes encryption
35 and or decryption functions implemented in part or whole in hardware, and hardware functions implemented in
36 programmable logic may be dynamically programmed by one or multiple protected software object; and or
37
38 may use any method to determine that there is an attempt to gain access to secret information within itself, and said
39 attempt may be physical and or logical analysis, and the response may be any action, using any method, including

1 disabling, temporarily and or permanently, part or all of itself and or invalidating in any way part or all of the secret
2 information that may be stored within secure memory storage devices; and or
3
4 may securely store information in encrypted and or clear code format in locations inaccessible to unauthorised
5 parties and or securely store information in encrypted format in locations that may be accessible to unauthorised
6 parties, and may detect tampering with stored information; and or
7
8 may have the capacity to securely monitor the usage of said protected software object; and or
9
10 may be loaded with information that is any one or multiple units of use, in any secure format, that may be securely
11 stored within said secret processing device and or securely in accessible external locations and said units of use may
12 be used to offset against use of one or multiple said protected software objects as determined by their said conditions
13 of use, said units of use may be adjusted in any way as they are used and may be used to credit various said
14 producer and or said protected software objects and or any other method that can be used to record directly and or
15 indirectly the payments that are due to various producers and any other interested parties;
16
17 may securely record the usage of said protected software object and the record may include a secure breakdown of
18 the usage on a producer and or product or any other basis, and said record in part or whole is non-volatile; and or
19
20 request and or compel the user of said PUCDPS to provide any necessary reports of usage to said service provider
21 and or to any other location; and or
22
23 confirm that said reports that have been received as required; and or
24
25 not require modification of the PUCDPS operating system; and or
26
27 not require special routines to intercept calls to said system operating system; and or
28
29 identify the type of said protected software object and act as required; and or
30
31 provide or have access to one or multiple tamperproof, non-volatile source of time and or date; and or
32
33 provide or have access to one or multiple tamperproof timers; and or
34
35 provide one or multiple method of identifying a particular tamperproof environment that may include the use of an
36 electronic signature; and or
37
38 provide one or multiple secret codes and or programs that are unique to a particular secure environment and or that
39 are common across particular groups; and or
40

- 1 provide one or multiple programs, that may be preprogrammed and or transferred as required that use secret
2 information unique to said secret processing device; and or
3
4 process multiple said protected software object in a multitasking environment and this may be transparent to said
5 User Controlled Data Processing System; and or
6
7 include functions, preferably implemented in reprogrammable secure memory, that may be edited and or modified
8 and or deleted and or expanded and or in any other way changed, in a secure manner and usually transparently to the
9 user of said PUCDPS, enabling externally supplied and appropriately configured said protected software object to
10 adapt the secure processes available to said PUCDPS and create one or multiple applications not currently available
11 to said PUCDPS and or that permits any current application to be dynamically adapted, and said adapt includes
12 dynamically reprogramming various hardware functions implemented in part or whole with reprogrammable logic
13 connections and or dynamically modifying decryption processes; and or
14
15 are programs and or data preprogrammed into the device and or transferred in encrypted format and or in clear code
16 that assist any other function that includes the processing of said protected software object; and or
17
18 include secure memory that stores various internal system routines and may be loaded with externally supplied
19 objects for decryption and or execution and or any other purpose; and or
20
21 may partition secure memory that forms part of said secure and secret processing system into secure system memory
22 and secure user memory, wherein programs within system memory may access those in user memory, however, user
23 programs may not access system memory on an unauthorised basis, furthermore, said user memory may be further
24 partitioned into multiple user partitions, wherein each user partition cannot affect information within other user
25 partitions.
26
- 27 3. A method of distributing software objects according to Claim 1, wherein said not practical may be interpreted as
28 multiple levels of difficulty depending on the requirements and may be too difficult:
29 for a normal user;
30 with disassembly of said parts that are not functionally limited,
31 with attempts at characterising encrypted information in the hope of breaking encryption methods;
32 with attempts at destroying the package to view the information within.
33
- 34 4. A method of distributing software objects according to Claim 1, wherein said Oscar compatible is any functional
35 limitation of part or all of a software object by any method of encryption, usually at a secure location remote to the
36 user, where part or all of the reversal of the encrypted information, by decryption and or any other method, occurs
37 within a secure environment directly and or indirectly attached to a user controlled data processing system such that
38 part or all of the instructions and or data of the software object reconstituted by said reversal are not accessible to
39 analysis by any unauthorised party and the execution of part or all of said instructions and or the processing (using
40 any method) of part or all of said data that is not accessible to analysis by an unauthorised party remains in part or

- 1 whole inaccessible to analysis by any unauthorised party. The result is that part at least of the functional limitation
2 placed on a software object is not compromised by the process of using said software object.
3
- 4 5. A method of distributing software objects according to Claim 1, wherein said Groover compatible is any
5 functional limitation of part or all of a software object by deletion of part or all of the information within the software
6 object, usually at a secure location remote to the user, where part or all of the reversal of the deletion, by any other
7 method, occurs within a secure environment directly and or indirectly attached to a UCDPS such that part or all of
8 the instructions and or data of the software object reconstituted by said reversal are not accessible to analysis by any
9 unauthorised party and the execution of part or all of said instructions and or the processing (using any method) of
10 part or all of said data that is not accessible to analysis by an unauthorised party remains in part or whole
11 inaccessible to analysis by any unauthorised party. The result is that part at least of the functional limitation placed
12 on a software object is not compromised by the process of using said software object.
13
- 14 6. A method of distributing software objects according to Claim 2, wherein said determine a response to said
15 conditions may be based on a plurality of information states within and or external to said secret processing device,
16 including the availability of one or multiple said units of measurement to offset against any requirements in said
17 conditions of use, appropriate entry of any data key, compliance with reporting requirements, validation of said
18 conditions of use supplied with said protected software objects against appropriate values stored within said secret
19 processing device.
20
- 21 7. An apparatus for distributing software objects, referenced a secret processing device, that may in part or whole be
22 integrated into the same integrated circuit (and or directly and or indirectly linked) as the system microprocessor of
23 said user controlled data processing system, and preferably does not interfere with the normal functions of said
24 system microprocessor, the secret processing device may also form an integral part of a multiprocessor system
25 microprocessor, part or all of said secret processing device may be integrated into any one or multiple devices
26 external to said system microprocessor and attached directly and or indirectly to said user controlled data processing
27 system;
28
- 29 said secret processing device includes one or multiple secure microprocessors and one or multiple blocks of secure
30 memory storage devices, that may be any type and mix, and may include secure direct memory access controller and
31 other functions as described, wherein said secret processing device may:
32
- 33 securely decrypt and execute and or process instructions and or securely decrypt and process data; and or
34
- 35 securely decrypt and execute and or process instructions and or securely decrypt and process data that complies with
36 part or all of the requirements of reversing functional limitations applied that are said Oscar compatible; and or
37
- 38 reverse any functional limitations applied that are said Groover compatible; and or
39
- 40 reverse part or all any functional limitations applying to said protected software object; and or

1
2 may decide to reverse one or multiple said functional limitations applied to one or multiple said protected software
3 objects, based on the said conditions of use said securely linked to said protected software objects, where said decide
4 is an autonomous decision, based in part at least, on secure processing of information internal and or external to said
5 secret processing device, and that as long as said the requirements of one or multiple said protected software objects
6 and or said secret processing device are complied with, the user of a said user controlled data processing system is
7 able to execute and or process one or multiple said protected software object on the same basis as if they were said
8 software object; and or
9
10 have the capacity to implement in part or whole, one or multiple hardware devices in programmable logic and
11 preferably programmable logic that may be rapidly erased in the event of tampering, and this includes encryption
12 and or decryption functions implemented in part or whole in hardware, and hardware functions implemented in
13 programmable logic may be dynamically programmed by one or multiple protected software object; and or
14
15 transfer into itself and or has transferred any part of one or multiple information that may be necessary to provide
16 any of the functions required by said protected software object; and or
17
18 access any information that may be located external to said secret processing device in order to provide any of the
19 functions required by said protected software object; and or
20
21 examine the said conditions of use said securely linked to said protected software object; and or
22
23 determine a response to said conditions of use; and or
24
25 respond to said conditions of use; and or
26
27 provide one or multiple area of secure memory that is not practical to analyse; and or
28
29 provide for partition of secure memory into one or multiple secure system partitions and one or multiple user
30 partitions whereby programs in said system partitions may access said user partitions, however, said user partition
31 may not access said system partition unless authorised, and or any particular said user partition may not access any
32 other said user partition unless authorised; and or
33
34 may transfer part or all any one or multiple said protected software object and or any other software objects from
35 unsecure to said secure locations for processing and or transfer any information from said secure location to said
36 unsecure location; and or
37
38 may securely decrypt part or all of decrypted parts of said protected software object and or any other encrypted
39 information within said secure locations; and or
40

1 may process part or all of one or multiple said protected software object in secrecy, including processing of part or
2 all of that information loaded in encrypted format and decrypted; and or
3
4 have the capacity to detect whether part or all of said protected software object have been tampered with; and or;
5
6 may perform secret encryption and or secret decryption in a manner that cannot be analysed, and this may be a
7 software and or hardware function; and or
8
9 have the capacity to implement in part or whole, one or multiple hardware devices in programmable logic and
10 preferably programmable logic that may be rapidly erased in the event of tampering, and this includes encryption
11 and or decryption functions implemented in part or whole in hardware, and hardware functions implemented in
12 programmable logic may be dynamically programmed by one or multiple protected software object; and or
13
14 may use any method to determine that there is an attempt to gain access to secret information within itself, and said
15 attempt may be physical and or logical analysis, and the response may be any action, using any method, including
16 disabling, temporarily and or permanently, part or all of itself and or invalidating in any way part or all of the secret
17 information that may be stored within secure memory storage devices; and or
18
19 may securely store information in encrypted and or clear code format in locations inaccessible to unauthorised
20 parties and or securely store information in encrypted format in locations that may be accessible to unauthorised
21 parties, and may detect tampering with stored information; and or
22
23 may have the capacity to securely monitor the usage of said protected software object; and or
24
25 may be loaded with information that is any one or multiple units of use, in any secure format, that may be securely
26 stored within said secret processing device and or securely in accessible external locations and said units of use may
27 be used to offset against use of one or multiple said protected software objects as determined by their said conditions
28 of use, said units of use may be adjusted in any way as they are used and may be used to credit various said
29 producer and or said protected software objects and or any other method that can be used to record directly and or
30 indirectly the payments that are due to various producers and any other interested parties;
31
32 may securely record the usage of said protected software object and the record may include a secure breakdown of
33 the usage on a producer and or product or any other basis, and said record in part or whole is non-volatile; and or
34
35 request and or compel the user of said user controlled data processing system to provide any necessary reports of
36 usage to said service provider and or to any other location; and or
37
38 confirm that said reports that have been received as required; and or
39
40 not require modification of the PUCDPS operating system; and or

1
2 not require special routines to intercept calls to said system operating system; and or
3
4 identify the type of said protected software object and act as required; and or
5
6 provide or have access to one or multiple tamperproof, non-volatile source of time and or date; and or
7
8 provide or have access to one or multiple tamperproof timers; and or
9
10 provide one or multiple method of identifying a particular tamperproof environment that may include the use of an
11 electronic signature; and or
12
13 provide one or multiple secret codes and or programs that are unique to a particular secure environment and or that
14 are common across particular groups; and or
15
16 provide one or multiple programs, that may be preprogrammed and or transferred as required that use secret
17 information unique to said secret processing device ; and or
18
19 process multiple said protected software object in a multitasking environment and this may be transparent to said
20 User Controlled Data Processing System; and or
21
22 include functions, preferably implemented in reprogrammable secure memory, that may be edited and or modified
23 and or deleted and or expanded and or in any other way changed, in a secure manner and usually transparently to the
24 user of said PUCDPS, enabling externally supplied and appropriately configured said protected software object to
25 adapt the secure processes available to said PUCDPS and create one or multiple applications not currently available
26 to said PUCDPS and or that permits any current application to be dynamically adapted, and said adapt includes
27 dynamically reprogramming various hardware functions implemented in part or whole with reprogrammable logic
28 connections and or dynamically modifying decryption processes; and or
29
30 are programs and or data preprogrammed into the device and or transferred in encrypted format and or in clear code
31 that assist any other function that includes the processing of said protected software object; and or
32
33 include secure memory that stores various internal system routines and may be loaded with externally supplied
34 objects for decryption and or execution and or any other purpose.
35
36 8. A method of distributing software objects according to Claim 7, wherein said determine a response to said
37 conditions may be based on a plurality of information states within and or external to said secret processing device,
38 including the availability of one or multiple said units of measurement to offset against any requirements in said
39 conditions of use, appropriate entry of any data key, compliance with reporting requirements, validation of said

1 conditions of use supplied with said protected software objects against appropriate values stored within said secret
2 processing device.

3

4

5 9. An apparatus for distributing software objects according to Claim 7, wherein said Oscar compatible is any
6 functional limitation of part or all of a software object by any method of encryption, usually at a secure location
7 remote to the user, where part or all of the reversal of the encrypted information, by decryption and or any other
8 method, occurs within a secure environment directly and or indirectly attached to a user controlled data processing
9 system such that part or all of the instructions and or data of the software object reconstituted by said reversal are not
10 accessible to analysis by any unauthorised party and the execution of part or all of said instructions and or the
11 processing (using any method) of part or all of said data that is not accessible to analysis by an unauthorised party
12 remains in part or whole inaccessible to analysis by any unauthorised party. The result is that part at least of the
13 functional limitation placed on a software object is not compromised by the process of using said software object.

14

15

16 10. An apparatus for distributing software objects according to Claim 7, wherein said Groover compatible is any
17 functional limitation of part or all of a software object by deletion of part or all of the information within the software
18 object, usually at a secure location remote to the user, where part or all of the reversal of the deletion, by any other
19 method, occurs within a secure environment directly and or indirectly attached to user controlled data processing
20 system such that part or all of the instructions and or data of the software object reconstituted by said reversal are
21 not accessible to analysis by any unauthorised party and the execution of part or all of said instructions and or the
22 processing (using any method) of part or all of said data that is not accessible to analysis by an unauthorised party
23 remains in part or whole inaccessible to analysis by any unauthorised party. The result is that part at least of the
24 functional limitation placed on a software object is not compromised by the process of using said software object.

25

26 11. An apparatus for distributing software objects according to Claim 7, wherein said protected software object is a
27 software object that has been reversibly functionally limited to be reversed in part or whole by functions provided by
28 said secret processing device.

29

30 12. An apparatus for distributing software objects according to Claim 7, wherein said conditions of use may be a
31 plurality of conditions securely linked to said protected software object that are extracted in part or whole by said
32 secret processing device and used to determine whether to reverse the said functional limitations applied to one or
33 multiple said protected software object.

34

35 13. A method of securely protecting and distributing software objects substantially as hereinbefore described with
36 reference to the drawings.

37

38 14. An apparatus for distributing software objects substantially as hereinbefore described with reference to the
39 drawings.

40

1 15. The steps, features, compositions and compounds disclosed herein or referred to or indicated in the specification
2 and/or claims of this application, individually or collectively, and any and all combinations of any two or more of
3 said steps or features.

INTERNATIONAL SEARCH REPORT

International Application No.
PCT/AU 97/00010

A. CLASSIFICATION OF SUBJECT MATTER		
Int Cl ⁶ : G06F 12/14		
According to International Patent Classification (IPC) or to both national classification and IPC		
B. FIELDS SEARCHED		
Minimum documentation searched (classification system followed by classification symbols) IPC: G06F 12/14		
Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched AU: IPC as above		
Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)		
C. DOCUMENTS CONSIDERED TO BE RELEVANT		
Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	WO-A-9522796 (INFOSAFE SYSTEMS INC) 24 August 1995 See whole document	1-15
X	WO-A-9321581 (SECURE COMPUTING CORPORATION) 28 October 1993 See page 10 line 18 to page 11 line 35 and page 18 line 35 to page 19 line 7	1-15
